At length the chemists set themselves to work in making numerous mercurial preparations, to some of which superior efficacy was imputed. It was as early as the year 1553, that lotions of sublimated mercury were first employed by Angerius Ferrerius. Two ounces of it were dissolved in six pounds of distilled water. With this mixture the whole body was washed and rubbed, excepting the head, breast, stomach, and arm-pits; and this method was continued once, twice, or thrice a day for ten days, according to the strength of the patient, and other circumstances. The patient was at the same time sweated most profusely; for sweating was conceived to assist in the cure, because the distemper was more easily overcome in the West Indies, where diaphoretic means had long been used in aid of guaiacum. Quicksilver girdles for the loins and wrists were also in fashion. The fumigations were made with mercury extinguished in turpentine, or else with cinnamon blended with inflammable ingredients.

John de Vigo was the first who avowed giving mercury internally, about the year 1535. The medicine that he exhibited in this manner was the *hydrargyrus nitratus ruber*, which had been previously praised both by Vigo himself and Nicholas Massa, as a most beneficial application to venereal ulcers. The violent effects of this preparation, when administered internally, soon brought it into disrepute, and then pills of crude mercury came into use.

If, however, the first employment was generally conducted with extreme caution and timidity, there were many exceptions, and afterwards, when the profession became more familiar with the method, they became of course bolder. For we learn that, after a time, the flagrant evils arising out of the improvident use of the medicine, and the frequent instances of death from its poisonous action, excited an universal clamour against it, and many preferred enduring the disease to the mercurial remedy. It is no wonder, therefore, that guaiacum, when brought into Europe in 1517, China-root in 1535, sassafras about the same time, and salaparilla a little afterwards, were received with wonderful applause, as delivering the afflicted from a dreaded distemper, and a more dreaded remedy. (See Foot on Lues Ven. lect. 19.) What degree of merit such medicines possess, we shall presently enquire.

As soon as it was ascertained that pharmaceutical preparations of mercury might be internally given, without the degree of danger formerly apprehended, myriads of secret formulæ began to be obtruded upon every town and every country of Europe. Among the most famous remedies were the *mercurius dulcis*; the common *Æthiops*; *mercurius alkalizatus* ground with oyster-shells; *mercurius antithifiscus* with dry balsam of Peru; *mercurius antiscorbuticus* with gum guaiacum; *mercurius dulcis* with manna; *mercurius diureticus* with juniper gum; and *mercurius catharticus* with scammony. Afterwards rougher preparations were made use of, such as *mercurius precipitatus albus*; a solution of red precipitate in aquafortis corrected, red precipitate, turbith mineral, green precipitate, besides numerous high sounding panaceæ. Even a solution of corrosive sublimate, mixed with barley-water, or water-gruel, was long ago execrated as "the vile practice of London quacks" by our countryman Wiseman.

With such a farrago of mercurial preparations it is hardly to be expected that any regular and rational plan of treatment could be pursued by the generality of the old practitioners.

LUES VENEREA.

tioners. The common methods were chiefly empirical, and it was not until towards the beginning of the eighteenth century, that the treatment of the venereal disease began to be regulated by scientific principles.

In the elegant edition of *Aphorismi* by Boerhaave, a full account may be seen of circumstances confirming the preceding statement.

Whoever will consult Wiseman, one of the most respectable authors we have in surgery, will find that the symptoms of the venereal disease were in general much more severe in his time than they are at present, and at the same time that the mode of practice was still much severer. In claps, large and repeated doses of drastic purges, calomel, and turpeth mineral were the medicines employed, even in the inflammatory state of the disease, and some turpentine remedies were given to complete the cure. Venereal sores were powdered with red precipitate, and dressed with the most acrid and stimulating applications. In confirmed syphilis, the hot salivating method of treatment was adopted; the patient was crammed into a small room heated with a stove; the admittance of fresh air was prevented by blankets put up at the door and windows; and the patient himself was surrounded with a screen. There he sat, half suffocated in his own hot putrid atmosphere, and was rubbed with mercurial ointment, until his tongue generally lolled out, and the inside of his mouth was covered with sloughs. In this hideous pickle it was customary for him to lie from twenty-five to thirty days.

It is no wonder, as Mr. Dease has observed, that many fell victims to this preposterous mode of treatment, few constitutions being able to endure it, and no constitution escaping without material and permanent injury.

Our English Hippocrates, the great Sydenham, lays it down as an axiom, that, as the venereal virus is of a very inflammatory nature, the principal end to be aimed at in the treatment ought to be evacuation. In gonorrhœa he advises strong drastic purges, which are to be perfomed for a long time. The first fourteen days of the disease he purges the patient every day; then every second day; and, towards the latter end of the case, twice a week. Should the cure advance but slowly, eight grains of turpeth mineral, given twice or thrice, at due intervals, Sydenham reckons extremely effectual. Where purgatives are rejected by the mouth, he substitutes clysters. Balsam of Mecca, or Cyprus turpentine closes the cure. He thinks injections do much more mischief than service; and is averse, in these cases, to the use of mineral waters, and decoctions of the woods.

As Sydenham does not account mercury a specific, in the cure of lues venerea, only inasmuch as it is possessed of a superior efficacy in exciting salivation, he considers as useless and hurtful all preparation, as bleeding, purging, or bathing, before putting the patient into a salivation. He thought that the less the patient was weakened, the greater was the probability of a cure. His whole attention, in the treatment, is to keep up a high degree of salivation. If the rubbing does not have this effect, he gives turpeth mineral, or calomel; and, of the latter medicine, he gives a dose once a week, for some months after the cure is apparently effected, for fear of a relapse. He is against carrying off, by purging, any remains of the spitting after the course is over; and, during the whole treatment, allows the patient such light meats as may be desired.

The methods of treating lues venerea, as laid down by Wiseman and Sydenham, were for a long time followed, throughout Europe, with no material variation. At length the celebrated Astruc gave one of the most elaborate treatises on this distemper ever published.

The treatment of a gonorrhœa he considers at three dif-

ferent periods. In the first, or inflammatory stage, he directs us to employ large and repeated bleedings; and thinks, that the indication for copious bleeding is as strongly pointed out in this case, as in that of a peripneumony, or dysentery. He orders large quantities of cooling emulsions to be frequently drunk, the bowels to be kept open with emollient glysters, opiates, if the symptoms are violent, cooling injections, fomentations, poultices to the penis and perineum, and a very slender regimen. In the second stage, when the inflammatory symptoms have subsided, after purging two or three times with jalap, diagridium, or calomel, he has recourse to mercurial frictions every second day, to be more immediately employed about the parts of generation and perineum. He continues the same severe regimen. In the third stage, he completes the cure by some of the turpentines, mineral, acidulated, vitriolic, or steel waters, or the common astringents. He reprobates astringent injections. In what he terms the dry gonorrhœa, he pushes the antiphlogistic treatment much farther; for he even bleeds every fourth hour.

In the cure of syphilis, Astruc prefers salivation by mercurial frictions. He enters into a long description of the necessary previous preparation; bleeding, purging, warm bathing, medicated broths, and slender regimen. He says, it is seldom we can dispense with less than ten baths; more generally, he orders twenty. After this course of bathing, the bleeding and purging must be repeated. He then has recourse to the mercurial frictions, which he so directs as to keep up unremittingly a full regular spitting, from two to three pints in twenty-four hours, until the cure is completed. The patient is then cleansed in a warm bath, and purged.

Not long after Astruc's work made its appearance, practitioners became extremely divided in opinion as to the method of administering the mercurial frictions, for the cure of lues venerea. Some of the most respectable followed the plan laid down by Astruc; while the greater number of practitioners in France followed the Montpellier method of extinction; that is, after having first made the patient take twenty or thirty warm baths, and kept him for some time on a very slender regimen, the frictions were so administered as not to raise any spitting, and thus continued for three or four months, until the venereal virus was totally eradicated.

The celebrated Van Swieten, in the fifth volume of his *Commentaries on Boerhaave's Aphorisms*, adopts, in a great measure, the opinion of his illustrious master in treating of this disease. In the treatment of gonorrhœa, if we except his disapprobation of bleeding, which he thinks is very seldom necessary, we find nothing new: for he follows the general mode of practice, and effects a cure chiefly by purgatives.

In the treatment of strictly venereal cases, he gives a preference to salivation raised by internal mercurials, instead of employing the unction. He thinks that the quantity of mercury, introduced into the system, is much better ascertained, when mercurius dulcis three times sublimed, or white precipitate, is made use of, in lieu of frictions with mercurial ointment. He considers that the quantity of mercury, introduced in this latter method, must be uncertain; and that as it does not pass out of the system as readily as saline mercurials, it may accumulate, and be deposited in dangerous quantities, in different parts of the body, and be productive of the worst consequences. But, above all other methods of curing the disease, Van Swieten prefers the well known solution of corrosive sublimate in brandy, or spirits. By this medicine, which was in general use in St. Mark's hospital,

hospital, Vienna, four thousand eight hundred and eighty persons are said to have been perfectly cured of the venereal disease, in the course of eight years, without undergoing any tedious preparation, or having any dangerous symptom intervene.

The ingenious author of the *Parallel of the different Methods of treating the Venereal Disease* (supposed to have been the physician Petit) is extremely severe in censuring this method of treatment, and asserts that, from repeated experience, he has found the administration of the solution to be very precarious, and by no means productive of the good effects so lavishly promised by the Vienna practitioners. See *Obs.* on the different Methods of treating the Venereal Disease, by W. Dease, 1779, the Introduction.

From these observations on the mercurial remedies employed, and plans adopted, by the old surgeons, in the treatment of syphilitic affections, let us pass on to the consideration of the practice of modern times, which has been vastly influenced by the doctrines promulgated by Mr. Hunter. The leading points of his theory having been already stated in the foregoing columns, we shall not repeat them at large in this place. Suffice it to say, that this surgeon inculcated, that when the venereal poison was absorbed, it contaminated the system at once, leaving only a disposition behind it, which is brought forth into action in various parts at various times; that the local cause of this disposition, and its effects, may be cured by mercury, but that the disposition itself cannot; and that parts, once cured, cannot be contaminated again from the same stock of infection.

It must not be dissimbled, that the theories of Mr. Hunter, respecting lues venerea are in some respects obscure and questionable. Much difficulty has been experienced in rightly comprehending his exact meaning; and he has even been accused of inconsistency and contradiction. Dr. Adams, in his *Commentary on Hunter's Treatise*, has published the substance of a conversation, which he once had with this famous character, with regard to the difficulty attending the comprehension of the doctrines in question. On this occasion, Mr. Hunter related the following case, to shew how easily his opinions might be understood, even by a person altogether unaccustomed to such inquiries.

"A gentleman," said Mr. Hunter, "who had been cured of a chancre at a distance from home, called to consult me whether he might consider himself as perfectly free from the disease. Whilst he was taking great pains to explain to me how he had been salivated, and how long he had continued the use of mercury, after the chancre was healed, I interrupted him by observing, that if he had continued the use of mercury till now, I could not pretend to say whether he was free from the disease—How then, said the gentleman, am I to ascertain my real situation?—If, replied I, you find no symptoms in the course of three months, the probability is that you will remain well, till you expose yourself to a new source of infection.

"In about six weeks he returned, with a sore throat and copper spots. I explained to him, that he should not blame his surgeon, who, even if he had known what was to happen, could not have prevented it. The patient went through a very necessary course of mercury, till he was cured of every symptom, and then demanded, with some impatience, whether he was then secure—You are secure, replied I, from every return on your genitals, and on your skin and throat; but as it is impossible for me to know whether your bones are contaminated, I cannot pretend to say whether you will have nodes in a few weeks' time. He now began to comprehend the doctrine, and submitted to await the result. In about six weeks he actually had nodes;

after the cure of which, by a severe salivation, I made no scruple to assure him that he was perfectly free from the disease."

According to Mr. Hunter's principles, then, if mercury were exhibited for ten years, it could not prevent the disposition, after it is once formed, from proceeding to action some time or another; and although this author admits that this remedy may altogether hinder the disposition from taking place at all, yet that it has no power of eradicated any forms of the disease, except what is positively in action, and consequently more or less palpable. And it was likewise a position in Mr. Hunter's theory, that the parts contaminated, or those to which the disposition was imparted, became thus infected all about the same time, and very soon after the first absorption of the virus into the constitution, the inference necessarily followed, that mercury could seldom avail in hindering the formation of the disposition, except in an early stage of the case. According to the Hunterian opinions, mercury given as a *preventive*, on any other principle, was entirely useless. The parts contracted the disposition soon after the virus had been absorbed into the system, unless, by good luck, mercury had been employed so early and efficiently as entirely to prevent such disposition from taking place. If it had not been used early enough, and with sufficient effect to prevent the formation of the disposition in the parts susceptible of contamination, these could not fail of falling afterwards, but at an uncertain period, into a palpable state of syphilitic action, and in that state alone were capable of being cured by mercury. The disposition, though it might have been prevented, could not be cured by mercury. That part of the doctrine, also, which inculcates that parts, which have been once cured, cannot be contaminated again from the same stock of infection, tends strongly to shorten a mercurial course; because, as the foregoing case illustrates, when one order of parts have been cured by mercury, there is no danger of a recurrence of the dilemma in them: and though the disposition may exist in another order of parts, and, of course, must come into action, it would be absurd to continue mercury on that account, both because this mineral absolutely has not the power of destroying the disposition, and it can never be known, *a priori*, whether these other parts are contaminated or not.

The employment of the term *disposition* has led to much dispute. Many have not been able to understand the word, and others have raised several objections to it. The critical examiners of Mr. Hunter's doctrine ask, how is it possible to prove that a venereal disposition has, or has not, existed at any particular time? If, after a certain course of mercury, and the consequent removal of a chancre, blotches should appear, then, says Mr. Hunter, a disposition had been formed, which no quantity of mercury could have destroyed. But, observe the critics, may we not, with at least equal probability say, that in such cases mercury had been insufficiently used? If, on the other hand, after such a course, no blotches should occur, the friends of the doctrine tell us, the secondary order of parts had not been contaminated; but, in this case, it may be contended by the opposite party, that the mercurial course had been judicious and efficient. It is insisted by Mr. Hunter's opponents, that the evidence of this incurable disposition cannot be proved: nor by his friends can it be justly and confidently assumed: for if it be action, then its coincidence with other actions is admitted contrary to their principles: if it be not action, then the disease which follows is motion without impulse, and effect without a cause. This opinion, indeed, with regard to the difference of disposition and action, it is maintained, was not

readily

steadily and uniformly contemplated by Mr. Hunter himself in his practice, or even in his theories; for he sometimes talks of the cure of lues venerea in the state of disposition, and generally continued the exhibition of mercury, after the disappearance of the symptoms. (See London Medical Review, No. 11, p. 248, 249.) For our own part, without undertaking to defend the inconsistencies into which Mr. Hunter has undoubtedly fallen, we have no hesitation in declaring our belief, that his opinions and doctrines in general concerning lues venerea, and the power of mercury over it, are the best and most rational that have ever been promulgated. In particular, we cannot concur with the anonymous critic quoted above, when he thinks it as reasonable to refer the perfection, or imperfection of the cure, to mercury having been sufficiently, or insufficiently used. We have known instances in which patients have been almost constantly employing mercury for twelve and eighteen months for the cure of local complaints, succeeded by sore throats and eruptions, and yet, after all this time, and after all this perseverance in the use of mercury, nodes on the cranium, skin, or ulna, have arisen. Certainly, when a patient has been for many months in a state of salivation, and has thereby got rid of all his palpable symptoms, we are not justified in concluding that because future complaints begin, these might have been hindered by a further continuance of the mercurial course. Mercury is so often used in immoderate quantities, and for so unreasonable a length of time, without preventing a succession of secondary symptoms, that we cannot bring our minds to believe, that the recurrence of the disease, in such cases, can be hindered by any judicious or practicable perseverance in the employment of this mineral. At the same time we are not such bigots to the Hunterian theory as to suppose, that the use of mercury ought not to be continued an instant after a chancre, or bubo, is either healed or apparently converted into a common sore. It is generally impossible to ascertain, with precision, the exact moment when venereal action ceases. The disposition, or contamination of other parts, may possibly sometimes happen later than Mr. Hunter supposed, and we have every reason to conclude that such disposition may be imparted at any time, while the venereal action in a chancre, or bubo, is not completely subverted. Mr. Hunter supposed, that the syphilitic poison could only be absorbed when blended with pus. Perhaps the virus may exist, and be taken up by the absorbents in other forms. The induration left after a chancre is healed is not always free from the venereal action, though not a drop of matter is now secreted; yet as there are so many inexplicable circumstances in certain cases of the present disease, it seems almost warrantable to believe that the virus may exist, and be imbibed by the absorbents, so as to impart the disposition to the distemper at later periods than Mr. Hunter conjectured, and under an additional number of states and circumstances. According to Mr. Hunter, the matter of secondary ulcers is not possessed of the specific venereal quality, and cannot produce the disease, when absorbed, as the matter of a chancre or bubo does. Supposing this to be true, whatever opinions may be entertained respecting the continuance of mercury, after the venereal action of a chancre or bubo has apparently ceased, there can be no diversity of sentiment in regard to the utility of persevering in that medicine, after secondary sores are either healed or have had their character entirely altered.

Having detailed the ancient practice, mentioned the forms in which mercury was formerly exhibited, and endeavoured to give some idea of the degree of power which this medicine possesses over syphilitic affections, it is our place to

make a few observations on the mercurial preparations, to which modern practitioners generally give the preference.

As long ago as the days of Berenger of Carpi, who, as we have recited, was the first person that ascertained the efficacy of mercury in the treatment of syphilis, it has been well known that this metal, in its reguline state, possesses no medicinal virtue. Its power of acting against disease only exists when it is in the state of a salt, or oxyd. Its preparations have also very different degrees of efficacy.

The most active of all the preparations of mercury is the oxygenated muriate, the oxymurias, or, as it is generally called, the corrosive sublimate, which is, in fact, a violent poison. We have already stated, that the celebrated Van Swieten was exceedingly partial to this medicine in syphilitic cases. He dissolved it in brandy, or alcohol, and diluting this mixture with a certain proportion of water, prescribed the remedy in a fluid state. The ordinary dose is a quarter of a grain every day; but the quantity may, in particular instances, be increased to half or three quarters of a grain every 24 hours. Sublimate is, even at the present time, usually prescribed after the manner directed by Van Swieten, the solution in alcohol being ordinarily taken, either in some warm milk, a decoction of sarsaparilla, or blended with some syrup, which vehicles are supposed to prevent the sublimate from disordering the stomach and bowels. Notwithstanding these correctives, this preparation of mercury often produces considerable sickness and griping pains, and it is reckoned extremely improper for patients labouring under pulmonary affections. It should only be tried in cases where the constitution is strong and free from much irritability. But the most important truth to be attended to is the decision of many experienced surgeons, that the corrosive sublimate, though a powerful medicine, has not so much efficacy in accomplishing a radical cure of syphilitic diseases, as several other more simple and mild preparations of mercury. Hence it is seldom exhibited by surgeons of the present time for the cure of primary venereal symptoms, except when particular circumstances are in the way of other more approved methods. The convenience and secrecy with which a solution of the corrosive sublimate may be taken, and the circumstance of a small phial of it being in some instances sufficient for the cure, may, perhaps, be reasons why it has been more extensively administered, than its comparative efficacy appears to justify.

The submurias hydrargyri, or calomel, is far less active than the oxymurias, or corrosive sublimate, and though not now very much employed in this country for the cure of unequivocal syphilitic complaints, it is, like every other preparation of mercury, anti-venereal, and was at one time commonly given. Whenever it is exhibited at present, it is almost always in the form of pills, containing from one to three grains. When the dose is larger, purging is generally excited, and little specific effect on the disease is the consequence. Hence, when calomel is prescribed with a view of producing a salivation, opium must generally be conjoined with it. Calomel has also been mixed with ointment, so as to form a dressing for venereal sores, or admit of being introduced into the system by being rubbed upon the skin. Attempts have likewise been made to cure syphilis by frictions with calomel on the gums, and inside of the lips and cheeks. However, violent and dangerous ptyalism having, in this manner, been sometimes produced, without the disease being radically cured, the method has fallen into disrepute. In the article FUMIGATION, we have described a powder, made with calomel, for the purpose of being applied to the surface of the body in the form of a vapour, or a subtile powder raised by heat.

Sometimes,

LUES VENEREA.

Sometimes, when patients cannot rub in mercurial ointment, or frictions alone have not sufficient effect, a grain of the hydrargyrus calcinatus, now called hydrargyri oxydum rubrum, is prescribed, and to prevent bad effects on the bowels, half a grain of opium is generally directed to be taken at the same time. The grey oxyd of mercury, formed by the trituration of quicksilver with fat, is the most common, safe, and effectual preparation for the cure of syphilitic complaints. A piece of this ointment, about as large as a nutmeg, is ordinarily rubbed into the surface of the body, for about half an hour before the fire. When there is a bubo in the groin, the leg and thigh, on the affected side, are generally preferred for the frictions; but when this is inconvenient, the ointment may be rubbed upon any other part of the body. Mercurial ointment, provided the fat is not rancid, which it is very apt to be, makes an eligible application to both primary and secondary venereal ulcers, when it is spread upon lint. The introduction of mercury into the constitution, by frictions with ointment, is one of the oldest and best methods. When the patient cannot rub in himself, the business may be done by an attendant, who must be provided with gloves, made of oil-skin, or pig's bladder, lest he salivate himself. The frictions are said to have the most effect when made along the inside of the limbs, where anatomy shews that the largest lymphatics are situated. It is always a prudent maxim to begin a course of mercury in a very gentle way, only small quantities of the ointment being at first ventured upon. Perhaps half a dram is enough to begin with. Nor need the frictions be made every day until the ability of the constitution to bear the medicine has been tried. Thus, the patient may commence with rubbing half a dram of the ointment on the inside of the leg. After letting one day intervene, he may make the second friction on the inside of the thigh. When another intervening day has elapsed, the third application of the ointment may be made to the hip and lower part of the abdomen. The fourth friction may be made on the arms, unless the patient should prefer beginning again on the leg. During such employment of the ointment, the patient, if convenient, should wash himself now and then in a warm bath, and have costiveness obviated by mild purgatives. The preceding method is generally commendable, because it removes all chance of too sudden and violent a salivation, as well as diminishes the peril, with which the administration of mercury is liable to be accompanied in particular constitutions. Though such is the most prudent plan to be followed in the generality of cases, it must still be remembered, that there are certain instances in which the affection of the system with mercury ought to be expedited, for the purpose of preventing the serious consequences, which might arise from the spreading of venereal ulceration in particular situations, as where a chancre threatens to destroy the whole glans, or an ulcer in the throat to eat away all the velum pendulum palati. In every case it is highly proper, that the patient should have some tenderness of the gums, and a copper taste in his mouth, as tests of his constitution being under the influence of mercury; but all violent salivations, attended with extreme soreness and sloughing of the mouth, and vast swelling of the face, are condemned as unnecessary, and in every respect blameable, by all the most judicious practitioners of the present time.

The grey oxyd of mercury, made by trituration of quicksilver with sugar or honey, composes the common pil. hydrarg. or blue pill, which, in ordinary cases, is the best mercurial medicine for internal use. It is given, either to assist the action of the ointment, or when the frictions cannot be executed. The common dose is ten grains every

night, opium being added when any griping or purging is excited.

Such are the preparations of mercury ordinarily used by British surgeons in the treatment of syphilis.

In addition to the foregoing directions, respecting the management of a mercurial course, there are many other circumstances to be observed. Every surgeon should be impressed with the importance of the patient keeping himself warm, and avoiding all exposure to damp and cold, during the employment of mercury. He should be recommended to keep to his room, and wear woollen stockings, and flannel drawers and waistcoat. Experience has proved, that exposure to the damp cold air sometimes determines the action of mercury violently either to the mouth, or the bowels, and materially lessens its effect upon the disease.

According to Mr. Hunter, when a course of mercury is about to be undertaken, we are to consider two things; first, the preparation and mode attended with the least trouble or inconvenience to the patient; and secondly, the preparation and mode of administering it, that most readily conveys the necessary quantity into the constitution. Mercury is carried into the constitution in the same way as other substances, either by being absorbed from the surface of the body, or that of the alimentary canal. It cannot, however, in all cases be taken into the constitution in both ways; for sometimes the absorbents of the skin will not readily receive it, at least no effect is produced, either on the disease, or constitution, from this mode of application. In this circumstance, mercury must be given by the mouth, although the plan may be very improper in other respects, and often inconvenient. On the other hand, the internal absorbents sometimes will not take up the medicine, or at least no effect is produced on the disease, or the constitution.

In such cases, all the different preparations of the medicine should be tried; for sometimes one succeeds when another will not. In some cases, mercury seems to have no effect, either applied outwardly, or taken into the stomach. Many surfaces seem to absorb mercury better than others; such are probably all internal surfaces and sores. Thirty grains of calomel, rubbed in on the skin, have not more effect than three or four taken by the mouth. Dressing small ulcers with red precipitate sometimes causes a salivation. Hunter on the Venereal Disease, p. 335, 336.

Besides the practicableness of getting the medicine into the constitution in either way, it is proper to consider the easiest for the patient, each mode having its convenience and inconvenience, depending on the nature of the parts to which it is applied, or on certain situations of life at the time. Hence, it should be given in the way most suitable to such circumstances.

In many, the bowels can hardly bear mercury at all, and it should then be given in the mildest form possible, conjoined with such medicines as will lessen, or correct its violent local effects, although not its specific ones on the constitution.

When mercury can be thrown into the constitution with propriety by the external method, it is preferable to the internal plan, because the skin is not nearly so essential to life as the stomach, and, therefore, is capable in itself of bearing much more than the stomach. The constitution is also less injured. Many courses of mercury would kill the patient, if the medicine were only given internally, because it proves hurtful to the stomach and intestines, when given in any form, or joined with the greatest correctors. Every one, however, has not opportunities of rubbing in mercury,

and is therefore obliged, if possible, to take it by the mouth. Hunter, p. 338.

Mercury has two effects, one as a stimulus on the constitution and particular parts; the other as a specific on a diseased action of the whole body, or of parts. The latter action can only be computed by the disease disappearing.

In giving mercury in the venereal disease, the first attention should be to the quantity, and its visible effects in a given time, which, when brought to a proper pitch, are only to be kept up, and the decline of the disease to be watched; for by this we judge of the invisible, or specific effects of the medicine, and know what variation in the quantity may be necessary. The visible effects of mercury affect either the whole constitution, or some parts capable of secretion. In the first, it produces universal irritability, making it more susceptible of all impressions. It quickens the pulse, increases its hardness, and occasions a kind of temporary fever. In some constitutions it operates like a poison. In some it produces a kind of hectic fever, that is, a small quick pulse, loss of appetite, restlessness, want of sleep, and a fallow complexion, with a number of consequent symptoms; but such effects commonly diminish on the patient becoming a little accustomed to the medicine. Mercury often produces pains like those of rheumatism, and nodes of a scrofulous nature. Hunter, p. 339, 340.

The quantity of mercury to be thrown into the constitution, for the cure of any venereal complaint, must be proportioned to the violence of the disease. However, we are to be guided by two circumstances, namely, the time in which any given quantity is to be thrown in, and the effects it has on some parts of the body, as the salivary glands, skin, or intestines. For mercury may be thrown into the same constitution in very different quantities, so as to produce the same ultimate effect; but the two very different quantities must also be in different times; for instance, one ounce of mercurial ointment, used in two days, will have more effect upon the constitution, than two ounces used in ten. The effects of one ounce, used in two days, on the constitution and diseased parts, are considerable. A small quantity, used quickly, will have equal effects, to those of a large one employed slowly; but if these effects are principally local, that is, upon the glands of the mouth, the constitution at large not being equally stimulated, the effect upon the diseased parts must be less, which may be known by the local disease not giving way in proportion to the effects of mercury on some particular part. If it is given in very small quantities, and increased gradually, so as to tend insensibly on the constitution, a vast quantity at a time may at length be thrown in, without any visible effect at all. Hunter, p. 341.

These circumstances being known, mercury becomes a much more efficacious, manageable, and safe medicine, than it was formerly thought to be; but, unluckily, its visible effects upon the mouth and the intestines are sometimes much more violent, than its general effect upon the constitution at large. These parts must therefore not be stimulated so quickly, as to hinder the necessary quantity of mercury from being used.

The constitution, or parts, are more susceptible of mercury at first than afterwards. If the mouth is made sore, and allowed to recover, a much greater quantity may be thrown in a second time, before the same soreness is produced. However, anomalous cases occur, in which, from unknown causes, mercury cannot at one time be made to

produce any visible effects; but afterwards, the mouth and intestines are all at once affected. Hunter, p. 342.

Mercury occasionally attacks the bowels, and causes violent purging, even of blood. This effect is remedied by intermitting the use of the medicine, and exhibiting opium. At other times, it is suddenly determined to the mouth, and produces inflammation, ulceration, and an excessive flow of saliva. To obtain relief in this circumstance, purgatives, nitre, sulphur, gum-arabic, lime-water, camphor, bark, kali sulphuratum, blisters, &c. have been advised. Mr. Pearson, however, does not seem to place much confidence in the efficacy of such means, and the mercury being discontinued for a time, he recommends the patient to be freely exposed to a dry cold air, with the occasional use of cathartics, Peruvian bark, and mineral acids, and the assiduous application of astringent gargles. "The most material objection, (says Mr. Pearson,) which I foresee against the method of treatment I have recommended, is the hazard, to which the patient will be exposed, of having the saliva suddenly checked, and of suffering some other disease in consequence of it.

"That the hasty suppression of a ptyalism may be followed by serious inconveniences, has been proved by Dr. Sylvester, (Med. Obs. and Inq. vol. iii.) who published three cases of persons who had been under his own care; two of whom were afflicted with violent pains; and the third scarcely retained any food in her stomach for the space of three months. I have seen not only pains, but even general convulsions, produced from the same cause. But this singular kind of metastasis of the mercurial irritation does not appear to me to owe its appearance to simple exposure to cold and dry air; because I have known it occur in different forms, where patients continued to breathe a warm atmosphere, but used a bath, the water of which was not sufficiently heated. Cold liquids, taken in large quantity into the stomach, or exposure of the body to cold and moisture, will also prove extremely injurious to those who are fully under the influence of mercury; whereas breathing a cool air, while the body is properly covered with apparel, has certainly no tendency to produce any distressing or dangerous consequences.

"If, however, a suppression of the ptyalism should be occasioned by any act of indiscretion, the remedy is easy and certain; it consists only in the quick introduction of mercury into the body, so as to produce a soreness of the gums, with the occasional use of a hot bath." Pearson on the Effect of Various Articles in the Cure of Lues Venerea, edit. 2. p. 163, 164.

Mercury, when it falls on the mouth, produces, in many constitutions, violent inflammation, which sometimes terminates in mortification. In these habits great caution is necessary. The ordinary operation of mercury does not permanently injure the constitution; but, occasionally, the impairment is very material; mercury may even produce local disease, and retard the cure of chancres, buboes, and certain effects of the lues venerea, after the poison has been destroyed. Hunter, p. 342.

When an immoderate and violent salivation is suddenly produced, the means in repute for lessening this accident are, bathing the feet in warm water, clysters, cathartics, and blisters. The application of pounded ice to the jaw, and washing the mouth and throat with cold acidulated gargles, are, perhaps, measures as serviceable as any that can be adopted.

In the article ERETHISMUS, we have described a dangerous state of the system, sometimes occasioned by the use of mercury, and producing death in the most sudden and unexpected

pected manner. This is a subject urgently requiring the attention of the practitioner; but as we have treated of it elsewhere, we shall here be content with referring to the above-mentioned part of the present publication.

Mercury occasionally gives rise to a most severe and extensive rash all over the body, attended with alarming indisposition. This complaint is noticed in the article ERYTHEMA, and is one with which every surgeon should be well acquainted.

The precise manner in which mercury acts in checking and curing syphilitic diseases, has been the subject of various conjectures. Some writers fancy that it must operate by neutralizing the virus, just as an alkali destroys an acid. Others, seeing that mercury only exerted an anti-venereal quality, when combined with oxygen, have endeavoured to account for the action of this mineral, by the quantity of oxygen which it conveys with it into the system. Against the first of these suppositions it is argued, that mercury cannot act by neutralizing the virus, since its effect would then always correspond with the quantity introduced into the system. This experience contradicts, and the Hunterian doctrines lead us to conclude, that the virus does not long remain in the constitution, after contaminating the parts, and communicating to them the disposition which is afterwards to come into action. Against the second opinion it may be observed, that though mercury has no effect in its simple state, yet those mercurial preparations which have the most power over syphilis, are such as are combined with the smallest quantity of oxygen. Besides, there are other substances which contain infinitely more oxygen than mercurial medicines, and yet have not gained the celebrity and confidence which surgeons place in mercury, as an antidote for syphilis. There can be no doubt, however, that the nitric and nitrous acids, the oxygenated muriatic acid, and the oxygenated muriate of potassa, substances which largely abound in oxygen, are in a certain degree anti-syphilitic, though they cannot be depended upon so much as mercury. With respect to the *modus operandi* of mercury, it was Mr. Hunter's belief, that this mineral produced in the constitution an irritation which counteracted the venereal and entirely destroyed it. *Treatise on Ven. Disease*, p. 365.

The indiserete and immoderate employment of mercury sometimes gives rise to diseases, which are very liable to be mistaken for continuations of the syphilitic affection, for which that remedy was at first prescribed. Mr. Hunter himself confesses that these cases puzzle considerably, it being difficult to say when the venereal action is absolutely destroyed. He observes, that such complaints are most common in the throat; for while a mercurial course is going on, and the ulcer on the tonsils healing, or even healed, these parts will sometimes swell, and excoriations occur and spread over the whole palatum molle. Mr. Hunter believed that such excoriations, as well as other appearances of disease coming on during the use of mercury, were seldom or never venereal. Hence he recommended mercury to be continued no longer than was sufficient to overcome the original syphilitic disease. In these cases, he thought that bark was often of service, and that it might be usefully given, either with the mercury, or after the mercurial course was over.

Frequently venereal abscesses will not heal up, though they have become considerably better; for while the syphilitic actions remained in the part, mercury disposed that part to heal; but under the mercurial course, the constitution and part had acquired another disposition, proceeding (to use Mr. Hunter's language) from a venereal and mercurial

irritation, affecting a particular habit of body, or part, at the time which new disposition differs from the venereal, mercurial, and natural, being a fourth disposition arising out of all the three. Mercury, when continued under such circumstances, acts as a poison, and makes the local disease grow worse and spread. Some of the fores, formed in this way, not only resist all means of cure, but often inflame, ulcerate, and produce hard callous bases, so as to put on a cancerous appearance. New diseases may arise from mercury alone, as swelling of the tonsils, unattended with any syphilitic diseases, thickening of the peritonsillar, and cedema, and firmness of the parts over the bones. These complaints, arising under a course of mercury, are too often regarded as venereal, and that mineral pushed to the utmost extent. If mercury has already been given sufficiently to cure the original disease, it ought to be now mixed and left off, and not continued for these incidental affection, which will be rendered worse by it. If, after the cure of such maladies, the venereal disease should begin to come into action again, mercury must be given a second time. Mr. Hunter suspected that the disorders of the tonsils and peritonsium, above alluded to, originated from scrofula, and he entertained a favourable opinion of bark and sea-bathing for their relief. P. 369—371. The terrible forms of disease, which we every day see syphilitic complaints converted into by rash local and mercurial treatment, are really deplorable. The worst phagedenic buboes, and destructive sloughing chancres, and other ulcers, are often more owing to the wrong continuance and immoderate exhibition of mercury, and bad local treatment, than any original fault in the habit.

From mercury, we proceed to notice a few of the other principal remedies which have obtained repute for their anti-syphilitic virtues.

Guaiaicum is the medicine with which the natives of the West Indies are said to have cured syphilitic affections before these diseases made their appearance in Europe. Many writers of the 16th century contended that guaiaicum was a true specific for the venereal disease; and the celebrated Boerhaave, in the 18th, maintained the same opinion. We learn from Mr. Pearson that he was first entrusted with the care of the Lock hospital in 1781. Mr. Bromfield and Mr. Williams were in the habit of reposing great confidence in the efficacy of a decoction of guaiaicum wood. This was administered to such patients as had already employed the usual quantity of mercury; but who complained of nocturnal pains, or had gummata, nodes, oses, and such other effects of the venereal virus connected with secondary symptoms, as did yield to a course of mercurial frictions. The diet consisted of raisins and hard biscuit; from two to four pints of the decoction were taken every day; the hot-bath was used twice a week; and a dose of antimonial wine and laudanum, or of Dover's powder, was commonly taken every evening. Constant confinement to bed was not deemed necessary; neither was exposure to the vapour of burning spirit, with a view of exciting perspiration, often practised, as only a moist state of the skin was desired. This treatment was sometimes of singular advantage to those whose health had sustained injury from the disease, long confinement, and mercury. The strength increased; bad ulcers healed; exfoliations were completed; and these anomalous symptoms, which would have been exasperated by mercury, soon yielded to guaiaicum.

Besides such cases, in which the good effects of guaiaicum made it to be regarded as a specific for lues venerea, the medicine was also formerly exhibited by some practitioners on the first attack of the venereal disease. The disorder, being

LUES VENEREA.

thus benefited, a radical cure was considered to be accomplished; and though frequent relapses followed, yet as these partly yielded to the same remedy, its reputation was still kept up. Many diseases, also, which got well, were probably not really venereal cases. Mr. Pearson seems to allow, that, in syphilitic affections, it may, indeed, operate like a true antidote, suspending, for a time, the progress of certain venereal symptoms, and removing other appearances altogether; but he observes, that experience has evinced that the unsubdued virus yet remains active in the constitution.

Mr. Pearson has found guaiacum of little use in pains of the bones, except when it proved sudorific; but that it was then inferior to antimony or volatile alkali. When the constitution has been impaired by mercury and long confinement, a thickened state of the ligaments, or periosteum, or foul ulcers, still remaining, Mr. Pearson says, these effects will often subside during the exhibition of the decoction. He says, it will often suspend, for a short time, the progress of certain secondary symptoms of the lues venerea; for instance, ulcers of the tonsils, venereal eruptions, and even nodes. Mr. Pearson, however, never knew one instance in which guaiacum eradicated the virus; and he contends, that its being conjoined with mercury, neither increases the virtue of this mineral, lessens its bad effects, nor diminishes the necessity of giving a certain quantity of it. Mr. Pearson remarks, that he has seen guaiacum produce good effects in many patients having cutaneous diseases, the ozæna, and serofulous affections of the membranes and ligaments. See Pearson on the Effects of various Articles in the Cure of Lues Venerea, edit. 2. 1807.

Mezereon was recommended by Dr. A. Ruffel for a particular class of venereal symptoms, in the following terms: "The disease, for which I principally recommend the decoction of the mezereon root as a cure, is the venereal node that proceeds from a thickening of the membrane of the bones. In a thickening of the periosteum, from other causes, I have seen very good effects from it: and it is frequently of service in the removal of those nocturnal pains with which venereal patients are afflicted; though, in this last case, excepting with regard to the pain that is occasioned by the node, I own I have not found its effects so certain, as I at first thought I had reason to believe. I do not find it of service in the cure of any other symptom of the venereal disease." (Med. Obs. and Inq. vol. iii. p. 194. 195.) Mr. Pearson, however, asserts, unequivocally, that mezereon has not the power of curing the venereal disease in any one stage, or under any one form, and if the decoction should ever reduce a venereal node, yet there will be a necessity for taking mercury in as large quantity, and for as long a time as if no mezereon had been exhibited. Cullen found this medicine of use in some cutaneous affections, but excepting an instance or two of lepra, Mr. Pearson has very seldom found it possessed of medicinal virtue, either in syphilis, or the sequelæ of that disease, serofula, or cutaneous affections. The root of sarsaparilla was brought into Europe about 1530. It was at first reputed to possess singular efficacy in venereal cases; but afterwards lost all its fame. Sarsaparilla was again brought into notice by Dr. W. Hunter, who advised Dr. Chapman to make trial of it in a bad case of phagedenic bubo; and the benefit obtained in this instance led Dr. Hunter to extend the recommendation of the medicine. Sir William Fordyce stated, that sarsaparilla would quickly relieve venereal head-achs and nocturnal pains, and, if persisted in, cure them; that, in emaciated or consumptive habits, from a venereal cause, it was the greatest restorer of appetite, flesh, colour, and strength, which he knew of; that

when mercurial frictions had been previously employed, it would generally complete the cure of disease of the throat, nose, palate, or spongy bones; and that it would promote the cure of blotches and ulcers, sometimes accomplish it, even without mercury; though, in this circumstance, there was danger of a relapse. Sir W. Fordyce said, sarsaparilla was of little use in chimeres; but when these, or buboes, would not heal, after the employment of mercury, it would often cure, and always do good. He allows, however, that in all venereal cases "sarsaparilla is not to be trusted to, unless preceded by, or combined with, the use of mercury;" and he thought sarsaparilla would probably always cure what resisted mercury. Medical Obs. and Inq. vol. i.

The celebrated Cullen considered sarsaparilla as possessing no virtues of any kind; for (says he) "tried in every shape I have never found it an effectual medicine in syphilis, or any other disease." Mat. Med. vol. ii.

Mr. Brownfield declares, that he never saw a single instance in which sarsaparilla cured the venereal disease without the aid of mercury, either given before, or in conjunction with it. (Pract. Obs. on the Use of Corrosive Sublimate, &c. p. 78.) Mr. Pearson also "contends, that sarsaparilla has not the power of curing any one form of the lues venerea;" but he allows that it may suspend for a time the ravages of that contagion, the disease returning if no mercury should have been used. This gentleman admits, also, that sarsaparilla will alleviate symptoms derived from the venereal virus. He maintains, that the exhibition of sarsaparilla does not diminish the necessity for giving less mercury. Nocturnal pains in the limbs, painful enlargements of the elbow and knee, membranous nodes, cutaneous ulcerations, and certain other symptoms, resembling venereal ones, are often experienced after a full course of mercury. Such complaints, Mr. Pearson allows, are greatly benefited by sarsaparilla, and exasperated by mercury; and he observes, that it is from these complaints having been mistaken for venereal ones, that the idea has arisen, that sarsaparilla has cured syphilis when mercury had failed. Mercury, and the venereal poison, may jointly produce, in certain constitutions, symptoms which are not strictly venereal, and are sometimes more dreadful than the simple effects of syphilis. Some of the worst of these appearances are capable of being cured by sarsaparilla, while the venereal virus still remains in the system. When this latter disease has been eradicated by mercury, sarsaparilla will also cure the sequelæ of a course of the other medicine. Pearson on the Effects of various Articles in the Cure of Lues Venerea, 1807.

China-root once obtained the character of being a certain specific for syphilitic complaints. Its reputation rose very high, in consequence of its having been reported to have cured the emperor Charles V. At present its medicinal virtues are estimated very low indeed; and it seems to have now lost all its advocates. It was first used in practice about the year 1535.

Cinchona, or the Peruvian bark, has no specific virtue in syphilitic cases, but, according to Mr. Pearson, if it has been alleged upon plausible grounds, that guaiacum possesses medicinal efficacy in venereal pains; sarsaparilla, where there are phagedenic ulcers; and mezereon, in cases where there are membranous nodes; so bark has a claim to praise for its salutary agency in incipient buboes, in ulcers of the tonsils, and in gangrenous ulcers from a venereal cause. This gentleman has seen venereal buboes reduced, though not cured, by it; syphilitic ulcers in the throat healed by it, though the disease recurred; and sudden mortifications of the penis from chancre terminate in a cure of the distemper, with the exhibition of bark, unassisted by mercury. In these last cases,

Mr.

LUES VENEREA.

Mr. Pearson conjectures, that, as the extinction of the venereal poison could not be ascribed to the specific virtues of the bark, the absorption of the virus must have been anticipated and prevented by the death of the part. This gentleman acknowledges, however, that there are gangrenous chancres met with, where, after the detachment of the sloughs, the specific disease in the part continues, and the ulcer spreads, so that mercury is indispensable.

Opium has been said to be a specific in venereal cases; and in the first volume of the Medical Communications, some facts were published in support of this opinion. But in the years 1784 and 1785, Mr. Pearson made several experiments on the virtues of opium in lues venerea, at the Lock hospital. These are related in the second volume of the preceding work. The result was very unfavourable to the character of opium as an anti-venereal. In a later work, the same gentleman observes that he has been long accustomed to administer opium with great freedom, during the mercurial course; and the experience of more than twenty years has taught him, that when this medicine is combined with mercury, the proper efficacy of the latter is not in any measure increased; that it would not be safe to rely upon a smaller quantity of the specific mineral, nor to shorten the mercurial course at all more, than where no opium has been employed. (On Lues Ven., p. 68, 69.) Though opium may possess no anti-syphilitic virtue, it is unquestionably useful on other principles, in many venereal cases. It often prevents mercury from disordering the stomach and bowels; and it will frequently lessen the irritability and restlessness produced by the introduction of mercury into the constitution. But, regarded as a specific for syphilitic affections, we may conclude with Mr. Hunter, that it has no effect, till mercury has done its best, or its worst. This latter surgeon owns that opium has certainly considerable effects in many diseases, both in such as are consequent to the venereal disease, and in others arising from different causes. It had long been a favourite medicine with him, not only as relieving pain, but as capable of altering diseased actions. In all cases attended with irritability, he says, a decoction of poppy heads, made into a poultice, is an excellent application. He tells us, he had even seen two doubtful syphilitic cases cured by the internal exhibition of opium: but on his trying this plan in an unequivocal case of venereal blotches and sore throat, so far was opium from producing the desired effect, that, after a perseverance of three weeks, the sores were rather worse. Treatise on Venereal Disease, p. 373.

Dr. Storck has related some cases, in which cicuta, or hemlock, is stated to have cured syphilis, when other remedies had failed. (Lib. ii. De Cicuta.) At present it seems to have lost its character, as possessing any specific virtue over the venereal disease. It is not, however, a medicine without its uses. According to Mr. Pearson, the extract and the powder of hemlock may be sometimes advantageously given in spreading irritable sores; whether they are connected with the active state of the venereal virus, or they remain after the completion of the mercurial course. Cicuta sometimes does good, when opium will not; and, therefore, Mr. Pearson thinks it may have other virtues than those depending upon its anodyne qualities. P. 75.

For remarks on the anti-venereal effects of *sassafras*, *juni-perus*, *bardana*, *saponaria*, *dulcamara*, *juglans*, *lobelia syphilitica*, *astragalus exscapus*, *ammonia præparata*, *barytes muriata*, &c. we must refer to Mr. Pearson's publication.

A decoction of the green rind of the walnut seems worthy

of more attention than several other articles. The last author says he has employed it, during many years, where pains in the limbs and indurations of the membranes have remained, after the venereal disease has been cured by mercury, and seldom without manifest advantage. P. 81.

The decoction of the woods and the Lisbon diet drink are famous prescriptions in syphilitic cases. Where the disease is doubtful, or mercury disagrees, or is done with, such remedies may certainly be often taken with benefit.

No. 1.

R. *Sarsaparillæ concisæ*.

Aquæ distillatæ, lib. x.

The powdered antimony and pumice stone are to be tied in separate pieces of rag, and boiled along with the other ingredients.

This last decoction is reckoned to be the genuine Lisbon diet drink, whose qualities have been the subject of so much encomium. Pharm. Chirurg.

The muriatic and sulphuric acids have been exhibited in venereal cases with some advantage, as they are capable of improving the appearance of syphilitic ulcers, and restraining for a time the progress of the disease.

But the nitrous and nitric acids have gained the greatest repute for their anti-venereal qualities. These acids have been tried by Dr. Rollo, Mr. Crunkthank, Dr. Beddoes, Mr. Blair, and many others, as substitutes for quicksilver, in the cure of lues venerea. The practice began with Mr. Scott, a surgeon in Bengal, who is said to have derived the idea from Girtanner, who suggested that the efficacy of the various preparations of quicksilver might arise from the oxygen which they contained.

A multitude of cases have been brought forward in favour of nitric acid, as an anti-syphilitic; but there are also some others adduced, which seem very decidedly to controvert its claims.

LUES VENEREA.

claims to that character. It should be carefully remembered, that it is the *nitric* acid, not the *nitrous*, which seems to deserve a further trial in syphilitic cases.

The common way of giving the nitric acid, at first, is to mix ʒj with a pint of distilled water, the mixture being sweetened with simple syrup. This quantity is to be drunk, at different times, in the course of twenty-four hours, through a small glass tube, which is used to keep the teeth from being injured. If no inconvenience is felt, the dose of the acid may be increased to ʒiſs, ʒij, and even, in certain cases, to ʒiij.

The acid is said to increase the appetite, and secretion of urine; to cause more or less thirst, a white tongue, fizy blood, and an increase in the actions of the whole system, but nothing like mercurial salivation is produced. It does not agree, however, equally well with all constitutions.

The nitric acid is beneficial both in the *primary* and *secondary* symptoms of the venereal disease; more so, however, in the former. But, in the latter, even mercury itself frequently fails, and proves hurtful, so that the nitric acid suffers no disparagement from this fact. A change is said to be produced on the disease, by the acid, in six or eight days, and a cure very often in little more than a fortnight.

The oxygenated muriate of potash, which contains an immense quantity of oxygen, is said by Mr. Cruikshank to be more efficacious than the nitric acid, in relieving venereal symptoms.

Richerand informs us, that experiments, confirming the superior efficacy of mercury, in the cure of syphilis, were made for the space of a year, in the hospital of the *Ecole de Médecine* at Paris, before a committee of gentlemen expressly appointed for the purpose. It is stated, that some patients derived only temporary relief from the oxygenated fat and nitric lemonade; that a very few got quite well; and that others, after appearing to be entirely rid of the disease, suffered such relapses as evinced the superiority of the ordinary method. *Nosographie Chir. tom. i. p. 352. edit. 2.*

It appears to us, that there is one very important circumstance made out by the trials of various medicines in the treatment of the venereal disease. According to the Hunterian opinions, we are to suppose that it is the invariable character of the distemper to proceed regularly from bad to worse, unless checked by the specific remedy, mercury. This doctrine is taught in some of the present schools, and seems to be adopted by Dr. Adams in his work on morbid poisons. Were this idea a matter of fact, it would be of material consequence in practice; for, in many difficult and ambiguous cases, we might often form a just decision, by observing whether the complaints recede at all, without the aid of mercury: since, if they do so, they cannot in reality be syphilitic. This assertion, however, is by no means established; and from the observations published by Pearson, and other writers, on the effects of different remedies on the disease, we are to conclude that it is erroneous. The remarks, which we have quoted above, tend to shew that, even under the mere administration of bark, venereal buboes and syphilitic ulcers in the throat may sometimes be healed. The testimony of Mr. Pearson also confirms, that the muriatic and sulphuric acids will improve venereal sores, and restrain for a time the progress of the disease. The committee at the *Ecole de Médecine*, we find, announce that some few cures were effected by oxygenated lard and nitric lemonade. These statements, joined with the large body of respectable evidence from several other quarters already

specified, cannot fail to induce a suspicion, that many medicines, besides mercury, have a certain degree of power in resisting the ravages of the venereal disease; and that even syphilitic buboes and ulcers will sometimes recede, look better, and heal, without mercury. We do not wish to insinuate, that these things are decisively established; the diagnosis of true venereal complaints being often so difficult, that men of great judgment and experience are liable to mistakes.

Observations on the Treatment of particular Symptoms.

Treatment of Chancres.—Before the virus has been taken up by the absorbents, a chancre is strictly a local affection, quite unattended with any contamination of other parts. In this state, there can be no doubt that there is a possibility of accomplishing a cure by destroying with caustic the sore, and adjacent part affected with the venereal action. Such an endeavour must be the more likely to succeed, when it is made while a chancre is small, and in an incipient state. The *argentum nitratum* is commonly employed for this purpose: but perhaps it might be preferable to use the *kali purum* and quicklime, which operate with more effect and quickness. Unfortunately, the period at which the absorption of the virus begins is so uncertain, that the foregoing method is scarcely ever deserving of such implicit reliance, that mercury need not be employed at all. Small pustules and ulcerated points on the penis are frequently destroyed with caustic, and a lasting cure is effected without mercury. Possibly some of these cases may not be venereal; and when the practitioner infers that he has succeeded in preventing the absorption of the virus, he may be deceived. In other instances, the endeavour to supersede all occasion for mercury, by extirpating a chancre with caustic, is only attended with a temporary appearance of success; ulcerations of the tonsils, and other symptoms, denoting a general affection of the constitution, coming on soon after the healing of the sore. Hence it is generally deemed prudent, not to be content with the attempt at extirpation with caustic, but to exhibit, at the same time, for a few weeks, the *pil-hydrargyri*. The mercury may sometimes, indeed, be given unnecessarily; but with its exhibition, and the caustic, the patient has a double chance of security against the extension of the disease to his constitution.

We shall first consider the topical application to chancres.

Mercurial ointments have been commonly used as dressings to chancres; but Mr. Hunter was of opinion, that if the mercury were joined with watery substances, instead of oily ones, the application, by mixing with the matter, would be continued longer to the sore, and would prove more effectual. This, he observes, is one advantage, which poultices have over common dressings. He has often used mercury rubbed down with some conserve instead of ointment, and it answered extremely well. Calomel used in the same way, and also the other preparations of mercury mixed with mucilage, or honey, answer the same purpose. Such dressings, according to Mr. Hunter, will effect a cure in cases which are truly venereal, and free from other morbid tendencies.

Some chancres are indolent, and require a little warm balsam or red precipitate to be joined with the mercurial dressing. Mr. Hunter says, that calomel mixed with salve is more active than common mercurial ointment, and is attended with better effects, when the case requires stimulants.

Solutions of blue vitriol, verdigris, calomel, &c. have been recommended. But Mr. Hunter very judiciously observes,

ferves,

LUES VENEREA.

serves, that, as all these applications are only of service in remedying any peculiar disposition of the parts, as they have no specific power over the venereal poison, and as such dispositions are innumerable, it is almost impossible to say what applications will be effectual in every instance. Some kinds of dressings will answer in one state of the fore; some in another. The parts affected are often found extremely irritable, in which circumstance the mercury should be mixed with opium or preparations of lead.

Mr. Hunter was an advocate for changing the dressings very often, because the matter separates them from the fore, so as to diminish their effects. He states, that changing the applications thrice a day, will not be found too often, particularly when they are in the form of an ointment.

When the venereal nature of a chancre is removed, the fore frequently becomes stationary, in which case Mr. Hunter observes, that new dispositions have been acquired, and the quantity of disease in the part has been increased. When chancres are only stationary, Mr. Hunter says, they may often be cured, by touching them slightly with the lunar caustic. No cicatrization, in this case, seems possible, till the contaminated surface, or the new flesh, which grows on that surface, has either been destroyed or altered. It is often surprising, how quickly the fores heal up, after being touched with the application.

At the same time that topical applications are made to chancres, mercury must be internally exhibited, both with a view of curing these ulcers, and preventing a lues venerea. Mr. Hunter believed, that the venereal disposition of the chancre would hardly ever withstand both local and internal mercurials.

When local applications cannot easily be made to chancres, as in cases of phymosis, there is a still greater necessity for giving mercury internally, by which means, the cure may in the end be effected.

Mercury should always be given internally in every case of chancre, let it be ever so slight, and even when the fore has been destroyed on its very first appearance. The remedy should always be exhibited the whole time of the cure, and continued some time after the chancre has healed; for, says Mr. Hunter, as there are, perhaps, few chancres without absorption of the matter, it becomes absolutely necessary to give mercury to act internally, in order to hinder the venereal disposition from forming. How much mercury should be thrown into the constitution in the cure of a chancre, with a view of keeping the system from being affected, cannot easily be determined, as there is no disease actually formed, by which we can be guided. Mr. Hunter states, that the quantity must in general be proportioned to the size, number, and duration of the chancres; or, in other words, proportioned to the opportunity, which there has been given for absorption.

The mercury, which is exhibited to act internally, may be conveyed into the system, either by the skin, or stomach, according to circumstances, and it should be so taken, as to produce a slight affection of the mouth.

Mr. Hunter next remarks, that when the fore has put on an healthy look, when the hard basis has become soft, and the ulcer has skinned over in a favourable manner, it may be regarded as cured.

The same distinguished writer notices, however, that in very large chancres, it may not always be necessary to continue the application of mercury, either for external or internal action, till the fore is healed, for the venereal action is just as soon destroyed in a large chancre, as it is in a small one, since every part of the fore is equally affected by the medicine, and, of course, cured with equal expedition.

But, in regard to cicatrization, circumstances are different, because a large fore is longer than a small one, in becoming covered with skin. Hence Mr. Hunter very justly explains, that a large chancre may be deprived of its venereal action long before it has healed; while, on the other hand, a small one may heal before the syphilitic affection has been destroyed. In the latter case, this gentleman represents it as most prudent, both on account of the chancre and constitution, to continue the employment of mercury a little while after the fore has healed.

Mr. Hunter, in the valuable work which he has left on the present subject, takes notice of sloughs, which occur in the tonsils, from the effect of mercury on the throat, and are apt to be mistaken for venereal complaints. He also mentions, that sometimes, when the original chancre has been doing well, and been nearly healed, he has seen new fores break out on the prepuce, near the fist, and assume all the appearance of chancres.

When, in the treatment of chancres, a bubo arises, while the constitution is loaded with a sufficient quantity of mercury to cure such fores, which medicine has also been rubbed into the lower extremity, on the same side as the bubo, Mr. Hunter suspected, that the swelling in the groin is not venereal, but is produced by the mercury. In these cases, he always preferred conveying mercury into the system in some other manner.

With respect to the treatment of chancres in women, since it is difficult to keep dressings on the parts Mr. Hunter advises the fores to be frequently washed with some mercurial solution, and speaks of one made with corrosive sublimate, as perhaps being the best, since it will act as a specific, and stimulant also, when this is requisite. When the chancres, however, are irritable, they are to be treated in the same manner, as similar complaints in men. When the fores extend into the vagina, this passage must be kept from becoming constricted, or closed, by the introduction of lint.

Sometimes, after a chancre and all venereal disease are cured, the prepuce continues thickened and elongated, so that the glans cannot be uncovered. Perhaps, the case is often without remedy. Mr. Hunter, however, very properly recommends trying every possible means, and he informs us, that the steam of warm water, hemlock fomentations, and cinnamon fumigations, are frequently of singular service.

When the thickening and enlargement of the prepuce cannot be removed by applications, all the portion, anterior to the glans penis, may be cut away. See PHYMOSIS.

Mr. Hunter has very ably explained, that chancres, both in men and women, often acquire, during the treatment, new dispositions, which are of various kinds, some retarding the cure, and leaving the parts in an indolent thickened state, after the cure is accomplished. In other instances, a new disposition arises, which utterly prevents the parts from healing, and often produces a much worse disease, than that from which it originated. Such new dispositions may lead to the growth of tumours. They are more frequent in men than women, and generally occur only when the inflammation has been violent from some peculiarity of the parts, or constitution. They have sometimes been considered as cancerous.

Among the diseases in question, Mr. Hunter notices those continued, and often increased inflammations, suppurations, and ulcerations, which become diffused through the whole prepuce, and also along the common skin of the penis, which become of a purple hue, attended with such a general thickening of the cellular membrane, as makes the whole organ

organ appear considerably enlarged. The same writer observes, that the ulceration on the inside of the prepuce will sometimes increase, and run between the skin and the body of the penis, and eat holes through in different places, till the whole is reduced to a number of ragged fores. The glans often shares the same fate, till more or less of it is gone. Frequently, the urethra in this situation is wholly destroyed by ulceration, and the urine is discharged some way farther back. The ulceration, if unchecked, at length destroys all the parts. In this acute case, prompt relief is demanded; but often the proper mode of treatment cannot be at once determined, owing to our ignorance, in respect to the exact nature of the peculiar cause of the disease. Mr. Hunter states, that the decoction of sarsaparilla is often of service, when given in large quantities, and that he has known the German diet-drink effect a cure, after every other remedy had failed.

Mr. Hunter also states, that the extract of hemlock is sometimes of service, and that he has known sea-bathing effect a perfect cure.

Sometimes, when such fores are healing, it becomes necessary to keep the orifice of the urethra from closing, by the introduction of a bougie.

Sometimes, after a chancre has healed, the cicatrix breaks out again, and puts on the appearances of the preceding sore. Occasionally, similar diseases break out in different places from that of the cicatrix. Mr. Hunter represents, that they differ from a chancre in generally not spreading so fast, nor so far; in not being so painful, nor so much inflamed; in not having such hard bases, as venereal sores have; and in not producing buboes. This writer was of opinion, that they were not venereal. They are very apt to recur.

Mr. Hunter does not specify any particular mode of cure for all these cases; but he mentions one instance, which seemed to be cured by giving forty drops of the lixivium saponarium, every evening and morning, in a basin of broth; and he adverts to another case, which was permanently cured by sea-bathing.

In some instances, after a chancre has healed, the parts, as Mr. Hunter remarks, do not ulcerate; but appear to become thickened and indurated. Both the glans and prepuce seem to swell, so as to form on the end of the penis a tumour, or excrescence, shaped very much like a cauliflower, and, when cut into, shewing radii, running from its base, or origin, towards the external surface. It is extremely indolent. It is not always a consequence of the venereal disease; for Mr. Hunter has seen it arise spontaneously.

No medicine seems to be at all likely to cure the disease: the only successful means is to amputate a considerable part of the penis, and then to keep a proper catheter introduced into the urethra.

Warts.—Chancres often induce a disposition to the formation of warts on the penis. We have in a former column stated our belief, that they are not venereal, though sometimes curable by mercury. Hunter seems to think them not syphilitic, and we never have seen any which could not be cured without mercury, and this without the continuance of the original disease in any other form.

These substances are excrescences from the body, they are not to be considered as truly a part of the animal, not being endowed with the common, or natural animal powers. Many trifling circumstances make them decay. An inflammation of the found parts round the wart, or stimuli applied to its surface, will often make it die. Electricity will also

induce an action in such excrescences, which they are not able to support; an inflammation is excited round them, and they drop off.

From this account, we must perceive, according to Mr. Hunter, that the knife and escharotics are not always necessary, although these modes will act more quickly than any other, especially when the neck of the wart is small. When such is the form of the excrescence, perhaps a pair of scissors is the best instrument; but, says the above distinguished writer, when cutting instruments of any kind are horrible to the patient, a silk thread, tied round the neck of the wart, will do very well. However, whichever plan is adopted, it is in general necessary to touch with caustic the base of the little tumour, after this has separated.

Mr. Hunter remarks, that escharotics act upon warts in two different ways, *viz.* by deadening a part, and stimulating the remainder, so that, by the application of escharotic after escharotic, the whole excrescence decays moderately fast; and it is seldom necessary to destroy them down to the very root, which is often thrown off. This, however, is not always the case, and the wart grows again, in which circumstance, it is proper to let the caustic destroy even the root itself.

The kali purum cum calce vivâ, lunar caustic, and blue vitriol, are all proper applications. But one of the best stimulants is the *argus aris* and powder of fava-leaves, mixed together.

Treatment of Buboes.—When a bubo is certainly a venereal one, and only in an inflamed state, an attempt is to be made to resolve the swelling. The propriety of the attempt, however, depends on the progress which the disease has made. If the bubo be very large, and suppuration appears to be near at hand, resolution is not likely to be effected. When suppuration has already taken place, Mr. Hunter much doubted the probability of any success attending the endeavour, which now might possibly only retard the suppuration, and protract the cure.

The resolution of these inflammations, says Mr. Hunter, depends principally on mercury, and almost absolutely on the quantity which can be made to pass through them. When suppuration has taken place, the cure also depends on the same circumstances.

The quantity of mercury, which can be made to pass through a bubo, is represented by Mr. Hunter as depending principally on the quantity of external surface for absorption beyond the bubo.

The mercury is to be applied to such surfaces as allow the remedy, when absorbed, to pass through the diseased gland. In this manner, the disease in the groin is subdued, and the constitution is less liable to be contaminated.

However, Mr. Hunter accurately notices, that the situation of many buboes is such, as not to have much surface for absorption beyond them; for instance, the buboes on the body of the penis arising from chancres on the glands, or prepuce.

When the bubo is in the groin, Mr. Hunter recommends surgeons to pay attention to whether the swelling is in the upper part of the thigh and groin, or on the lower part of the belly, before Poupart's ligament, or near the pubes. When the buboes are situated on the body of the penis, the absorbents leading directly from the seat of absorption are themselves diseased. When the bubo is in the groin, and at the upper part of the thigh, we may conclude that the lymphatics, both from the penis and thigh, run to the affected gland. When the bubo is high up, or on the lower part of the belly, before Poupart's ligament, probably the absorbents,

absorbents, which arise from about the groin, lower part of the belly and pubes, pass through the bubo. When the bubo is far forward, the absorbents of the penis and skin about the pubes pass through the swelling. Mr. Hunter contends, that the knowledge of these circumstances is very necessary, in order to apply mercury in the most advantageous situations.

The utility of rubbing the mercury into surfaces, the absorbents of which lead through the bubo, must be obvious, when it is considered, that the medicine cannot pass to the common circulation without going through the diseased parts; that it must promote the cure, as it passes through them; and that it also prevents the matter, which has already passed, and is still continuing to pass into the constitution, from acting there. Thus the bubo is cured, and the constitution, at the same time, preserved.

Mercury alone, however, is not always capable of effecting the cure of buboes.

When the inflammation rises very high, bleeding, purging, and fomenting, are generally recommended. When the inflammation was erysipelatous, Mr. Hunter had a high opinion of bark; and when it was serofulous, he used to recommend hemlock, and poultices made with sea-water.

The same eminent writer also takes notice of the fact of emetics sometimes occasioning the absorption of buboes, even after they contain matter.

1. *Resolution of the Inflammation of the Absorbents on the Penis.*—Though there is not surface enough beyond the bubo, for rubbing-in a sufficient quantity of mercury, to prevent the effects of absorption, Mr. Hunter still advises this surface to be kept constantly covered with mercurial ointment. In consequence of the surface in question being so small, more mercury must also be conveyed into the system by the mouth, or frictions on some other part. Mr. Hunter observes, that this is necessary, both in order to prevent a lues venerea, and to cure the parts themselves. The quantity of mercury must be regulated by the appearances of the original complaint, and the readiness with which the disease gives way. The same method, he adds, is to be followed in women, and the ointment should be kept continually applied to the inside and outside of the labia.

2. *Resolution of Buboes in the Groin.*—The inflammation of the absorbent glands is to be treated on the same principle as that of the vessels. In the first case, however, we are able to make a larger quantity of mercury pass through the diseased parts. When the bubo is in the groin, the mercurial ointment is to be rubbed on the thigh. This surface, as Mr. Hunter remarks, will in general absorb as much mercury as will be sufficient to resolve the bubo, and preserve the constitution from being contaminated; but when resolution does not readily take place, the same author advises us to increase the surface of friction, by rubbing the ointment upon the leg.

When the bubo is on the lower part of the belly, the ointment should be rubbed also on the penis, scrotum, and belly. The same plan should be followed when the bubo is still more forward.

Mr. Hunter states, that when the bubo gives way, the mercurial frictions must be continued, till it has entirely subsided, and, perhaps, longer, on account of the chancre, which may not yield so soon as the bubo. After the bubo has supplicated, Mr. Hunter is doubtful, whether rubbing-in mercury is useful, or not.

3. *Resolution of Buboes in Women.*—When the swellings are situated between the labia and thigh, Mr. Hunter recommends the mercurial ointment to be rubbed-in all about the anus and buttock, from which parts the absorbents probably

run through the seat of the disease. When the buboes are in the round ligaments, the surface for absorption will not be large enough, and more mercury must be internally given, or rubbed into other surfaces.

When the bubo is in one of the inguinal glands, the same plan is to be adopted as in the same case in men.

4. *Buboes in unusual Situations.*—When buboes form in the arm, or arm-pit, in consequence of the absorption of venereal matter from wounds on the hands, or fingers, mercurial ointment should be rubbed on the arm and forearm. Mr. Hunter adds, however, that this surface may not be sufficient, so that it may be proper to convey more mercury into the system in other ways. He states, that he has seen a true venereal chancre on the middle of the lower lip, attended with a bubo, on each side of the neck, under the lower jaw, close to the maxillary gland. The swellings were resolved by applying mercurial ointment to them, and the chin and lower lip.

5. *Quantity of Mercury necessary for the Resolution of a Bubo.*—Mr. Hunter observes, that the quantity of mercury necessary for the resolution of a bubo, must be proportioned to the obstinacy of the complaint; but that care must be taken not to extend the employment of the medicine so far as to produce certain effects on the constitution. When the bubo is in a situation which admits of a large quantity of mercury being rubbed in, so as to pass through the swelling, and when the complaint readily yields to the use of half a dram of mercurial ointment every night, the mouth not becoming sore, or at most only tender, the above author thinks it sufficient to pursue this course, till the gland is reduced to its natural size. In this manner, the constitution will probably be safe, provided the chancre, which may have caused the bubo, heals at the same time. When the mouth is not affected in six or eight days, and the gland does not readily resolve, then two scruples, or a dram, may be applied every night; and, continues Mr. Hunter, if there should still be no amendment, even more must be rubbed in. In short (says he) if the reduction is obstinate, the mercury must be pushed as far as can be done without a salivation.

When there is a bubo on each side, so much mercury cannot be made to pass through each, as the constitution in general will not bear this method. However, Mr. Hunter sanctions the plan of minding the forecets of the mouth with in this kind of case; though, he adds, that it is better to let the buboes proceed to suppuration, than to load the system with too much mercury.

When the situation of buboes will not allow an adequate quantity of absorbed mercury to pass through them, the frictions must be continued in order to affect the constitution; but, according to Mr. Hunter, more mercury in this case will be requisite, than when the remedy can be made to pass directly through the diseased gland.

Many buboes remain swifter, without either coming to resolution, or suppuration; and, notwithstanding every attempt to promote these changes, the glands become hard and scirrhous. Mr. Hunter conceived, that cases of this sort are either serofulous at first, or become so as soon as the venereal disposition is removed. He advises the use of hemlock, sea-water poultices, and sea-bathing.

6. *Treatment of Buboes which suppurate.*—The suppuration of buboes frequently cannot be prevented by any known means. They are then to be treated, in some respects, like any other abscess. Before opening buboes, Mr. Hunter conceived it was advantageous to let the skin become as thin as possible, as a large opening would then become unnecessary, and no measures would be requisite for keeping the skin from closing, before the bottom of the sore had healed.

Mr. Hunter thinks it doubtful, whether the application of mercury should be continued through the whole suppuration. He was inclined to continue it; but in a smaller quantity.

There has been much dispute, whether a bubo should be opened, or allowed to burst of itself, and whether the opening should be made with a cutting instrument, or caustic. On this subject, Mr. Hunter remarks, that there is no peculiarity in a venereal abscess to make one practice more eligible than another. The surgeon, he says, should in some degree be guided by the patient. Some patients are afraid of caustics; others, of cutting instruments. But when the surgeon has the choice, Mr. Hunter expresses a preference to opening the bubo with a lancet, in which method no skin is lost. But, he observes, that when a bubo is very large, and there will be a great deal of loose skin, after the discharge of the matter, he thinks that caustic may, perhaps, be better, as it will destroy some of the redundant skin, and occasion less inflammation than what is caused by an incision. The *kali purum*, with the *calx viva*, is the caustic commonly employed.

After the bubo has been opened, surgeons usually poultice it as long as the discharge and inflammation are considerable, and then they employ dressings, which must be of such a quality, as numerous undescribable circumstances may indicate. The use of mercury, in the mean while, is to be continued, both to make the bubo heal, and prevent the bad effects which might otherwise arise from the matter continually absorbed. The mercury should also be so rubbed in, as to pass, if possible, through the diseased groin.

The mercurial course is to be pursued till the sore is no longer venereal. But, in general, since this point is difficult to ascertain, the mercury must be given till the part has healed, and even somewhat longer, when the bubo has healed very quickly; for the constitution is afterwards very apt to become contaminated.

However, mercury is not to be continued thus long in all cases; for, as Mr. Hunter explains, buboes often assume, besides the venereal, other dispositions, which mercury cannot cure; but will even exasperate.

Consequences of Buboes.—Sometimes the sores, when they are losing, or entirely deprived of the venereal disposition, become changed into ulcers of another kind, and, most probably, of various kinds. How far it is a disease arising from a venereal taint, and the effects of a mercurial course jointly, says Mr. Hunter, is not certain. This writer suspected, however, that the nature of the part, or constitution, had a principal share in the malady.

Mr. Hunter observes, that such diseases make the cure of the venereal affection much more uncertain, because, when the sore becomes stationary, or the mercury begins to disagree, we are ready to suspect that the virus is gone; but this is not always the case. Perhaps the action of the venereal poison is only suspended, and will commence again as soon as the other disease ceases.

In these cases, Mr. Hunter recommends attacking the predominant disease; but he allows there is difficulty in ascertaining its nature, and finding out whether it is venereal, or not.

The same author also acquaints us, that he has seen some buboes exceedingly painful and tender to almost every thing that touched them, and the more mild the dressings were, the more painful the parts became.

In some instances, the skin only seems to become diseased. The ulceration spreads to the surrounding integuments, while a new skin forms in the centre, and keeps pace with the ulceration, so that an irregular sore, which Mr. Hunter

compares with a worm-eaten groove, is formed all round. It appears only to have the power of contaminating the parts which have not yet been affected; and those which have readily healed.

When buboes become stationary, and seem little inclined to spread, attended with a sinus or two, hemlock, joined with bark, is, according to Mr. Hunter, the medicine most frequently serviceable. It is best to use it both externally and internally. The same author also speaks favourably of *sarsaparilla*, sea-bathing, and sea-water poultices. He states, that at the Lock Hospital, gold-refiners' water has been found a useful application; that, in some cases, drinking large quantities of orange-juice, and in others taking mezezon, have been found serviceable.

Treatment of secondary Symptoms.—Before treating of this subject, it may be as well to recapitulate a few of the leading points in Mr. Hunter's doctrine.

1. Syphilitic matter, after being absorbed into the system, circulates with the blood, and is thrown out by the common emunctories; but in its progress it may contaminate other parts of the body, and give them a disposition to disease.

2. When this disposition is given, the diseased action does not follow till a certain time, which varies according to the constitution and other circumstances; but never happens while the constitution is under a mercurial irritation.

3. When the disposition has taken place, the action may be suspended by mercury; but the disposition will remain, and the action shew itself at some period after the mercurial irritation has ceased.

4. When the action has begun in an order of parts it may be cured, and will not return in the part, or that order of parts from the same stock of infection.

5. But the diseased action may take place in another order of parts, if that other order has been contaminated; and, in this order, it must be treated as in the former.

6. When the diseased action has taken place and been cured in the part first infected, in the throat and fauces, the skin, and the bones or periosteum, the subject may be said to be free from the disease, as far as our knowledge has hitherto traced it.

7. The usual time of the skin or fauces taking on the diseased action is, on a medium, six weeks after the mercurial irritation that cured the first symptoms has subsided; and in the bones about twice that time.

8. Whatever doubtful appearances may arise on the skin, throat, or bones, during the mercurial irritation, under which chancres, or buboes are giving way, they are certainly not venereal: and even if such secondary symptoms appear after that mercurial irritation has ceased, but earlier than the period specified in the preceding proposition, they are to be regarded with doubt.

9. If no secondary symptoms appear for three months after the mercurial irritation has ceased, and the constitution has not in the mean time been occupied by any other disease, we have for the most part no reason to apprehend any thing in the skin or throat from that stock of infection.

Lastly, there are uncommon instances, in which the secondary symptoms occur sooner or later than the periods above stated. See Hunter's Treatise, and Adams on Morbid Poisons, p. 159, 160.

The treatment of secondary symptoms consists almost entirely of the judicious employment of mercury. Frictions with the ointment are generally the most preferable; but sometimes the pill hydrarg. oxydi rubri, the solution of the oxymercurate, or the administration of mercury by fumigation (see FUMIGATION), may be proper and advantageous. The continuance of the mercurial course must always be suspended,

suspended, when the effects produced are attended with too much violence or disorder. Opium may be given to lessen and check the diarrhœa, which sometimes arises from mercury, and both weakens the patient and diminishes the specific action of that mineral on the distemper. Sometimes other medicines will be useful, either given after the mercury is done with, while it is omitted for a time, or even in conjunction with it. This may be said of bark, cicuta, opium, farsaparilla, and the diet-drinks already specified. Whatever doubts may prevail respecting the antivenereal qualities of nitric acid, none remain with regard to its utility in meliorating the state of many complaints, which may exist after the syphilitic action has been entirely subdued by a previous exhibition of mercury. But in our general observations we have already been so full in our directions for the management of a mercurial course, and in our account of the effects of other medicines in cases of syphilis, that it would be the most superfluous prolixity to enlarge on this subject.

There is one question, however, that presents itself as deserving consideration, namely, how long a mercurial course ought to be continued? We find that it was one of Mr. Hunter's opinions, that when venereal matter is absorbed, it may produce in parts a disposition to the disease, or, in other words, a state of contamination, which, though it might have been hindered by the timely effects of mercury, and may now be kept from going into action as long as the system is under the influence of mercury, yet cannot be cured, but must some time or another proceed to action, or a state of palpable disease. In this condition alone it is curable. We observe, however, that Mr. Hunter, in his practice, is not altogether regulated by this principle; for in his directions for the cure of a chancre, he recommends mercury to be followed up some time after the sore is cured, which medicine being supposed not to be capable of curing the disposition that may be formed, (and if formed at all, must have formed ere this,) the method, according to reason, can be of no service. We cannot pretend to deliver an opinion whether the practice is positively right or the theory wrong. One thing or the other must be the case. But it is our duty to state that the generality of surgeons think it prudent to go on with mercury a certain time after ordinary chancres are healed. But in the treatment of secondary symptoms we believe the perseverance in mercury, after all palpable syphilitic mischief is removed, is utterly wrong and unnecessary. In other respects, the mercurial course for the relief of secondary symptoms is to be conducted exactly in the same manner as in cases of chancre or bubo, and according to the directions given in our general observations. Should the secondary symptoms in the throat, skin, mouth, or nose, have taken place and been cured by mercury, we may assure the patient that whatever appearances may now present themselves in these parts, the complaints cannot be really syphilitic. Therefore the continuance of mercury is not indicated. But though we may venture to predict that the disease will not recur in this first order of parts, we cannot promise as much with respect to the second order, viz. the bones, periosteum, and tendons. Whether these have contracted the disposition, or, in other words, are contaminated or not, can never be known *à priori*. If they have contracted the disposition, this cannot be cured by mercury, but will, some time or other, take on the syphilitic action, or, in other terms, fall into a state of obvious and palpable disease. It is only in this last condition that mercury can exert its beneficial power in effecting a permanent cure. Were this medicine given under the idea of preventing syphilitic mischief, it might indeed delay the coming on of the complaints, but after the disposition has been formed, they must sooner or later follow. Mercury was supposed by

Hunter to be sometimes capable of preventing the disposition from being formed at all, if exhibited in an early stage of a chancre, before the virus has been absorbed. But as much absorption, and the consequent disposition for the disease in certain parts take place at an early period of the case, all perseverance in mercury for the prevention of any more secondary symptoms is, according to the Hunterian tenets, altogether fruitless. If the soft parts or first order have been cured, we cannot consider our patient safe, respecting the bones, periosteum, and tendons, or second order, till a medium of at least six weeks after the last mercurial irritation has ceased. Of this the patient should always be warned. The affections of this second order of parts generally consist of nodes and pains. But it is not every swelling or pain in a suspected bone that is really venereal. Mercury itself will sometimes bring on painful affections and enlargements of the bones. Even when nodes are syphilitic, it often happens that no continuance nor quantity of mercury will totally remove the swelling. Such medicine is only to be continued till we have reason to infer all syphilitic action in the part is subdued. Whatever degree of thickening or enlargement may now remain is only of a common nature, does not demand mercury, and frequently admits of being materially lessened, or even entirely removed, by blisters, if care is taken to keep up a discharge from the excoriated surface with the savine cerate.

Some other cases, connected with the subject of lues venerea, will be considered in the articles PHIMOSIS and PARAPHIMOSIS. See also GLEET, GONORRHOEA, &c.

LUESIA, in *Geography*, a town of Spain, in the province of Aragon; 20 miles S.W. of Jaca.

LUFF, a sea-term, the same with *loof*.

LUFFA, in *Botany*, the Arabic name of an herb of the Cucumber family, *Momordica Luffa*, Linn. Sp. Pl. 1433. Vessing. Ægypt. 48. t. 50, 51. Cavanilles, in his *Icones*, v. 1. 7. t. 9, 10, has applied it generically to a plant called by him *Luffa fetida*, a native of the East Indies, with which he thinks it probable that the above *Momordica* may agree in generic characters. Willdenow has adopted this *Luffa*, in his Sp. Pl. v. 4. 383. How far the difference in its stamens, whose anthers are all separate, and which are accompanied by five abortive filaments, may serve to keep it distinct, we very much doubt. As to the fruit, it appears nearly to agree with *Momordica Operculata*.

LUG, in *Agriculture*, a long measure of land, the same with pole or perch, sixteen feet and a half. In Gloucestershire, it however signifies a land-measure, of six yards, or a rod, pole, or perch of six yards. It is a measure by which ditching and other similar operations are performed in that district. This term is likewise applied to the stick by which the work is measured. It is sometimes called *log*.

LUG-a-Leaf, a name used in some parts of England for the *rhomboides* of Rondeletius, and the *rhombus non aculeatus squamifolius* of Willughby.

We have it on our own shores; and the Cornish people, who frequently catch it, call it the *lug-a-leaf*. See PLEURONECTES *Plateffa*.

LUG-sail, in *Sea Language*, is a square sail, hoisted occasionally on the mast of a boat or small vessel, upon a yard which hangs nearly at a right angle with the mast. These are chiefly used in the *barca longas*, navigated by the Spaniards in the Mediterranean.

LUGA, in *Geography*, a town of Russia, in the government of Petersburg, on a river of the same name; 80 miles S. of Petersburg. N. lat. 58° 25'. E. long. 29° 30'.

LUGANO, or LAURA, a territory of Italy, ceded to the Swiss cantons in 1513; it is environed by the districts of

Mendris Lugarus, Bellinzona, and the duchy of Milan; it is fertile and populous, about eight leagues long and five broad, lying in N. lat. 46°, and is divided into quarters, containing 16 market towns and villages, and 53,000 inhabitants. This territory produces pasture, corn, fruit, and silk; olives are in great abundance. It is now ceded to Italy.—Alfo, the capital of the fore-mentioned bailiwick or district, which is a small, tolerably built, trading town, delightfully situated round the curve of a bay, and backed by a succession of hills, rising in gentle swells to a considerable height; in front a bold mountain clothed with forest projects into the lake, of which a noble branch extends to its right and left. To that spot boats of various sizes are continually passing and repassing, its base being perforated with *cuniculi*, or caverns, to which the inhabitants send their meat, and all sorts of provision, where it is kept untainted for seven or eight days, and the wine preserved with delicious coolness. The heats are moderated by the surrounding hills, and the cool breezes from the lake. It is no less sheltered from the Alpine blaits, which, chilled by the neighbouring snows, would otherwise destroy the temperature of this equal climate. Olive, almond, and all the southern fruits ripen here to perfection. Lugano is the emporium of the greater part of the merchandize which passes from Italy over the St. Gothard, or the Bernardin. At the end of autumn, the Swiss mountaineers bring down numerous herds of cattle for sale, and return with less bulky commodities. The town contains about 8000 inhabitants; most of the houses are built of tuff-stone; the residence of the capitano, or governor, is a low building; and on the walls are the arms of the twelve regent cantons. On an eminence above the town stands the principal church, remarkable only for the beautiful carvings in stone round the doors and rose-window, and for the delicious prospect from its towers. In the cloister of the Recollists is a capital picture attributed to Luvino; their church is handsome, and the screen is ornamented with the paintings of the Passion by the same master. The palace of the Marquis de Riva contains a few good pictures; 16 miles N.W. of Como. N. lat. 45° 50'. E. long. 8° 53'. Cox's Switzerland, vol. iii.

LUGANO, *Lake of*, a lake adjoining to the town above described, about 25 miles in length, and from two to four in breadth; its form is irregular, and bending into continued sinuities. From Porto, a small village, situated at its southern extremity, an arm of the lake bends northward, and discharges itself into the Lago Maggiore, by means of the river Trifa. It is scarcely possible, says Mr. Cox, to imagine a more perfect or greater variety of beauties than this noble piece of water affords. The vast overhanging woods, the bold precipices, the transparency of the water, unite to form a scenery in the highest degree luxuriant. This lake is about 190 feet perpendicular higher than the lake of Como and Lago Maggiore. The two last mentioned lakes are of the same level, and about 240 feet higher than the city of Milan. Cox. See LAKE.

LUGAR BEN, a town of Prussia, in Natangen; 36 miles S.E. of Koigsberg.

LUG R-NUEVO, a town of Spain, in Valencia, on the coast; eight miles S. of Alicante.

LUGDE, or LUBE, a town of Westphalia, in the bishopric of Paderborn, on the Emmer; 24 miles N.N.E. of Paderborn. N. lat. 51° 55'. E. long. 9° 18'.

LUGDUNUM, in *Ancient Geography*. See LYONS.

LUGDUNUM Batavorum. See LEYDEN.

LUGGS, the English name for a peculiar species of insect, found in great plenty on the shores of Cornwall. It is of the nature of the *scelopendra*, and is called by Mr. Ray *vermis*

scelopendroides. It grows to twelve inches long, and has instead of legs nineteen pair of stiff bristles, all which stand toward the head part of the creature. The tail is at least five inches long when full grown, and has no mark of them. Its body is rounded, and much resembles the body of the common earthworm, and is of a flesh-colour, or pale red. It has no forelegs.

LUGMON, in *Natural History*, a name given by the people of the Philippine islands to a species of turtle, the female of which has a tuft of red feathers, of a pale blood colour, on her breast, which have greatly the appearance of a wound, so much that any body would really be deceived.

LUGNAQUILLA, in *Geography*, mountains of Ireland, in the county of Wicklow.

LUGNY, a town of France, in the department of the Seine and Loire, and chief place of a canton, in the district of Mâcon; 10 miles N. of Mâcon. The place contains 1133, and the canton 12,776 inhabitants, on a territory of 17½ kilometres, in 19 communes.

LUGO, JOHN DE, in *Biography*, a learned Spanish Jesuit and cardinal, was born at Madrid in 1583. He gave early proofs of his attachment to the introductory parts of learning, and was sent to study the law at Salamanca, where he entered the society of Jesuits, thereby following the example of his brother, though contrary entirely to the wish of his father. Upon the death of the father, the two sons divided a very large estate that had fallen to them among the Jesuits of Seville and Salamanca. He became professor of philosophy at Medina del Campo, then professor of divinity at Valladolid, and afterwards he filled the divinity chair at Rome. In 1643 he was raised to the dignity of cardinal by pope Urban VIII. without his knowledge, and he died at the age of seventy-seven, in the year 1660. He was the author of seven folio volumes, chiefly in theology and morals, of which a few tracts only have any degree of merit, such as "De Virtute et Sacramento Penitentiae," and "De Justitia et Jure." He is, however, particularly celebrated as being the person who brought the virtues of bark into notice, which he introduced into France in the year 1650, and which, under the name of "Cardinal Lugo's powder," he administered gratis to the poor, but obliged the rich to purchase with its weight in gold. Bayle.

LUGO, *Lucus Augusti*, in *Geography*, a very ancient town of Spain, in the province of Galicia, which, in the time of the Romans, was the centre of one of those jurisdictions that were named "Conventus." At present it is the see of a bishop, suffragan to St. Jago, and worth 155*l.* sterling. It is situated on an eminence near the banks of the Minho, 13 leagues from its source. Here several councils have been held; and among others, one in 564 to regulate the limits of the bishoprics of Galicia and Portugal. It is at most three miles in circumference: and the streets are tolerably handsome and well paved. It has 12 squares, three fountains, and five gates. The walls are ancient, but in good repair. The city contains a cathedral, several churches and convents, the bishop's palace, a college, a hospital, and an asylum. The civil administration is composed of an alcalde major, a regidor, and several district alcaldes. The cathedral is a very ancient building of Gothic architecture, with a modern portal. Lugo is supposed to contain more than 4600 inhabitants. They work up wools in this town, but not enough to send any out of the country. In its territory is a number of thermal springs, temperate and boiling. Wheat, barley, rye, and maize, are produced in the environs; and many large flocks of sheep are to be seen. The Minho supplies trout, salmon, and lampries. Lugo is distant from St. Jago 13 leagues. N. lat. 43° 21'. W. long. 7° 32'.—Alfo, a town

town of Italy, in the Veronese; eight miles N. of Verona.—Also, a town of Italy, in the Paduan; 10 miles E. of Padua.—Also, a town of Italy, in the department of the Lower Po; 15 miles S. of Ferrara.

LUGOS, a town of Hungary; 37 miles S.W. of Colofvar.—Also, a town of Hungary, in the bannat of Temesvar, on the Temes; 23 miles E. of Temesvar.

LUGUBRE, *Fr.* in *Musie*, a term which implies gloomy, melancholy, dejected.

LUHÄNGO, in *Geography*, a town of Sweden, in the province of Tavastland; 60 miles N.N.E. of Tavastland.

LÜHEA, in *Botany*, so named by Willdenow, in compliment, as we presume, to F. K. Freyherr von der Lühe, who published at Vienna, in 1797, a German hymn to Flora. His poetry ought to be very fine, as we hope it is, to merit so magnificent a plant.—Willd. Sp. Pl. v. 4. 1434.—Ciafs and order, *Polyadelphia Polyandria*. Nat. Ord. *Columniferae*, Linn. *Malvaceae*, Juss.

Gen. Ch. Cal. Perianth inferior, double; the outer of nine equal, linear leaves, channelled at the back; inner in five deep, lanceolate segments, internally smooth, naked, and coloured. Cor. Petals five, longer than the calyx, broad, roundish, wavy, crenate, veiny. Nectaries five, stalked, pencil-shaped, hairy. Stam. Filaments numerous, hairy, united into five sets at their base; anthers incumbent, roundish, smooth. Pist. Germen roundish, or conical, with five angles, hairy; style columnar, thick, shorter than the stamens, smooth upwards; stigma orbicular, broad, depressed, with several radiant furrows. Peric. Capsule of five cells. Seeds winged.

Eff. Ch. Calyx double; the outer of nine leaves; inner in five deep segments. Petals five. Nectaries five, pencil-shaped. Style one. Capsule of five cells. Seeds winged.

1. *L. speciosa*. Willd. Nov. Act. Soc. Nat. Scrut. Berol. v. 3. 410. t. 5.—Native of lofty mountains in the Caraccas, from whence we have a specimen, gathered by Dr. J. Marter, to whom, though we do not meet with his name, the Vienna gardens are indebted for many of the finest plants published by Jacquin. From him we learn what is mentioned above respecting the capsule and seeds, about which Professor Willdenow had no information. We have had no opportunity of consulting his original account in the memoirs of the Berlin Society, which is here cited on his own authority in his *Species Plantarum*.

This, the only known species, is a tree, 20 or 30 feet high, with alternate, round, brown branches, downy when young. Leaves alternate, on short, thick, downy stalks, roundish-oblong, pointed, slightly heart-shaped and a little unequal at the base, three or four inches long, unequally and sharply serrated; smooth and naked above; white with dense stellated down, furnished with three prominent ribs, and numerous transverse parallel veins, beneath. Flowers white, large and handsome, not many together, in downy, terminal, simple clusters. The calyx and partial stalks are clothed with dense pubescence, of a rusty hue in the dried specimen.—This plant is closely allied in habit and fruit to the *Pterospermum* of Schreber and Willdenow (*Pentapetes suberifolia* and *acerifolia* of Linnaeus); the differences in their flowers however seem essential, especially as the calyx of *Pterospermum* is simple.

LU-YNY, in *Geography*, a town of Russian Poland; 24 miles W. S.W. of Owruca.

LUICHEN, a city of China, in Quang-tong, situated in a fertile and pleasant country, near the sea. N. lat. 28° 58'. E. long. 110° 8'.

LUIDA, in *Botany*, Adanson v. 2. 492, was so called by that writer after Mr. Edward Lwy, the correspondent of Ray, who is mentioned in his *Synopsis* as the discoverer of several mosses and other plants in Wales. The supposed genus however will neither immortalize him, nor its whimsical author, being made up of various species of *Hypnum*, *Bryum*, *Splachnum*, &c. characterized by having some leaves triangular and some orbicular! Mr. Lwy disappears, by what Ray says of him, in the preface to the second edition of his *Synopsis* and elsewhere, to deserve more permanent commemoration.

LUIGI Rossi, in *Biography*, one of the earliest and most voluminous composers of cantatas in the seventeenth century. He is celebrated in 1640 by Pietro della Valle, in his letter to Guidiccioni, for his grave canonette, particularly that which begins "Or che la notte del silenzio amica."

Many of his cantatas are preserved in all the collections which include the music of the last century, particularly in the Brit. Mus. Bibl. Harl. 1265 and 1273, and in Dr. Aldrich's Collection, Christ church, Oxon.

His cantata, "La Fortuna," in the Museum collection, No. 1265, is of an immeasurable length. The recitative, however, with formal closes, has pleasing expression in it, that still live. No *da capo*, or sign of reference, appears in his cantata, and he writes twice or three times over the same air; a trouble which these expedients would have spared. He seems to have started several flimsy divisions, which afterwards became common; and, indeed, it appears from his cantatas, that as soon as secular music had divested itself of the pedantry of perpetual canons, fugues, and multiplied parts, another vice crept into the art, by the frequent and excessive use of divisions. Luigi, in songs for a single voice, has some of this kind as long as those in modern bravura airs.

In the Magliabecchi library at Florence, we found a scene of oratorio called "Giuseppe Figlio di Giacobbe, opera spirituale fatta in musica da Aloigi de Rossi, Napolitano, in Roma." And under the name of *Rossi* many of his compositions may be found in the museum.

Luigi, in his motets that are preserved in the Christ-church collection, appears to have been as able to write a *cappella*, in many parts with learning, as with elegance in few.

LUIGNA, in *Geography*, a town of Spain, in Asturias; 20 miles N.W. of Oviedo.

LUI-LUNG-TA. See SECHO.

LUING, or LONG ISLAND, one of the smaller western islands of Scotland, between Scarba and Kerrera.

LUINI, BONERRO, of Brescia, in *Biography*, an opera singer in soprano, who had been in Russia and other foreign countries, and acquired great wealth, but dissipated great part of it by play. Yet, after losing ten thousand pounds in one night of the money which he had gained *en sa vie*, he was still said, in Italy, to be very rich.

LUIS, ST, in *Geography*, a town of South America, in the government of Buenos Ayres, and province of Cordova; 170 miles S.W. of Cordova. S. lat. 32° 15'. W. long. 67° 12'.—Also, a town of South America, in the province of Meyes; 72 miles N.W. of Trinidad.—Also, a mission of Spanish monks in New Albion; 15 miles N.E. of Punta el Eleros.—Also, a town of New Navarre; 50 miles S. of Cala Grande.

LUIS de la Paz, ST, a town of Mexico, in the province of Mechoacan; 100 miles N. of Mechoacan. N. lat. 21° 50'. W. long. 102° 15'.

LUIS de Maranon, ST. See ST. FELIPE.

LUIS de Potosi, St., a city of Mexico, in the province of Guasteca, pleasantly situated, and environed with rich gold mines. The town is handsome and well built, considerable in size, and populous. The streets are straight and neat, the churches magnificent; and the inhabitants, who are chiefly Indians, possessing all the conveniences and comforts of life; 190 miles N.N.W. of Mexico. N. lat. 22° 25'. W. long. 103° 6'.

LUIS de Zacatecas, a town of Mexico, capital of the province of Zacatecas, the see of a bishop, and residence of a governor; 240 miles N.N.W. of Mexico. N. lat. 22° 50'. W. long. 103° 46'.

LUI-SHIN, in *Mythology*, the Jupiter of the Chinese, or spirit that presides over thunder. The figure of it has the wings, beak, and talons of an eagle. In his right hand he holds a mallet, to strike the kettle-drums with which he is surrounded, whose noise is intended to convey the idea of thunder; while his left is filled with a volume of undulating lines, very much resembling those in the hands of some of the Grecian Jupiters, and evidently meant to convey the same idea, *viz.* that of the thunder-bolts, and lightning.

LOUISIANA, in *Geography*, a district of Spain, in Andalusia, three leagues from Ecija, settled in 1791 by a colony of Germans, who built houses in an uniform plan, allotting to each house a portion of land, which constituted a village; but the houses are already beginning to fall into ruin.

LUISINUS, Louis, in *Biography*, a physician, was born at Udina, in the state of Venice, where he obtained considerable reputation about the middle of the sixteenth century, and was not less distinguished by his acquisitions in literature, than by his medical skill. He was author of the following works: "Aphorismi Hippocratis hexametro carmine conscripti," Venice, 1552; "De compefendis animi affectibus per moralem philosophiam et medendi artem, Tractatus in tres Libros divisus," Basle, 1562; "Aphrodisiacus, sive de Lue Venerea, in duos Tomos bipartitus, continens omnia quæcumque hæcenus de hac re sunt ab omnibus Medicis conscripta," Venice, 1566, folio. The first volume contained an account of the printed treatises on the lues up to that year; the second, published the year following, comprehended principally the manuscript works on the subject, which had not then been committed to the press. Eloy Dict. Hist. de la Médecine.

LUISNANSBERG, in *Geography*, a town of Sweden, in Westmanland; 48 miles N.W. of Stroemsholm.

LUJULA, in *Botany*, &c. See *OXALIS Acetosella*.

LUK, in *Geography*, a town of Bohemia, in the circle of Saatz; 6 miles E. of Carlsbad.

LUKAU, a town of Moravia, in the circle of Znaim; eight miles W.N.W. of Znaim.

LUKAWETZ, a town of Bohemia, in the circle of Czaflau; 28 miles S.W. of Czaflau.

LUKE, St., in *Sacred Biography*, one of the evangelists, and the writer of the gospel bearing his name, and also of the book of the Acts of the Apostles. Concerning his profession and country, previously to his conversion to Christianity, there is a difference of opinion among both ancient and modern authors. The first mention of him in the books of the New Testament occurs in his own history. (Acts, xvi. 10, 11.) When the apostle Paul was again, a second time, in Greece, it appears, from Acts, xx. 1-6, that St. Luke was with him; and that he accompanied Paul from Greece through Macedonia to Philippi, and went with him from thence to Troas. It further appears from the sequel of the history in the Acts, that he accompanied the apostle to Jerusalem, and remained with him there. When the

apostle was sent a prisoner from Cæsarea to Rome, Luke was in the same ship with him, and staid with him at Rome during the whole interval of his two years' imprisonment in that city. Of this fact we have also collateral evidence from the epistles of St. Paul written at this time. (2 Tim. iv. 11. Philem. v. 24.) And if Luke the beloved physician, mentioned Col. iv. 14, he the evangelist, this passage affords additional proof of his being then with the apostle. Some have also supposed that he is the person mentioned 2 Cor. viii. 18, as "the brother, whose praise is in the gospel throughout all the churches." Dr. Lardner, with his usual industry and accuracy, has collected the testimonies of various ancient writers concerning the evangelist Luke; and from these he deduces several inferences that serve to settle his profession and country, and to correct the mistakes of other authors. The notion which some have entertained, that he was a painter, is without foundation, as it is not countenanced by ancient writers. The learned Grotius and J. Wettstein have suggested, that he was a Syrian and a slave, either at Rome, or in Greece; and that having obtained his freedom, he returned to his native place, Antioch; where he became a Jewish proselyte, and then a Christian. This opinion is also rejected by our author; who observes, that the account given of this evangelist by Eusebius, and by Jerom after him, that he was a Syrian, and a native of Antioch, is not supported by the authority of Irenæus, Clement of Alexandria, Tertullian, or Origen, nor indeed by any other writer before Eusebius. Cave and Mill have intimated, that Luke was converted by Paul at Antioch; but it is alleged, on the other hand, that if Luke had been a Gentile, converted by Paul, he would have been always uncircumcised, and unfit to be the companion of Paul. For the apostle would not have allowed the Greeks or Gentiles of Antioch, or any other place, to submit to that rite. Besides, no hints occur in the Acts, or in the epistle of St. Paul, that Luke was his convert. It has been doubted by several learned men, whether the evangelist Luke was a physician. Dr. Lardner allows, that the distinguishing character of "beloved physician" (Col. iv. 14.) has occasioned a difficulty, which, however, he thinks, is not insuperable; and he conceives it probable, that Luke the evangelist was by profession a physician. That St. Luke was a Jew by birth, or at least by religion, our author argues from his being a constant companion of Paul in many places, particularly at Jerusalem. If he had been an uncircumcised Gentile, some exceptions would have been made to him, which we do not find from St. Paul's epistles, or the Acts, to have been the case; and besides, he follows the Jewish computations of times, such as the passover, the pentecost, and the fast. (See Acts, xii. 3. xx. 6. 16. xxvii. 9.) In this opinion, that St. Luke was a Jew, many learned and judicious moderns, as Mr. L. Bafnage and J. A. Fabricius, concur; and Dr. Lardner thinks, that it ought not to be questioned. Moreover, he was probably an early Jewish believer, soon after Christ's ascension, if not a hearer of Christ, and one of the 70 disciples. The most ancient writers speak of Luke as a disciple of the apostles. Some have reckoned him one of the Seventy, others have thought him to be Lucius, mentioned by St. Paul in the epistle to the Romans, and others have supposed, that he was one of the two disciples that met Jesus in the way to Emmaus. If Lucius be the evangelist Luke, which is an opinion adopted by several learned writers, we may conclude, that he was a Jew, and related to the apostle. We may know his character, and, in part, his history, from Acts, xi. 19-21, and xiii. 1-4. He was an early Jewish believer after Christ's ascension,

ascension, and together with others was very serviceable in preaching the gospel, at an early period, to Jews and Gentiles out of Judea. And if the other disciple, who accompanied Cleopas in the way to Emmaus, be Luke the evangelist, he was a disciple and eye-witness of Jesus Christ; though we do not allow him to be one of the 70. It appears further, that St. Luke was for a considerable time a constant companion of St. Paul; and that he was also acquainted with other apostles. It is probable, that St. Luke died a natural death; because none of the most ancient writers, such as Clement of Alexandria, Irenæus, Origen, Eusebius, and Jerom, say any thing of his martyrdom. Gaudentius, bishop of Brescia, about the year 387, observes, that in his time it was generally said, that Luke and Andrew finished their course at Patræ in Achaia, but without adding that it was by martyrdom: and if St. Luke be called a martyr, the appellation may be understood in a general sense, as equivalent to confessor, or a great sufferer for the gospel. Cave says (Hilt. Lit. p. 25.) that Luke lived a single life, and died in the 84th year of his age, about the year of Christ 70, but of what death is uncertain. Philostorgius informs us, that in the reign of the emperor Constantius, the reliques of St. Luke were translated from Achaia to Constantinople; and therefore it must have been a general persuasion in those times, that St. Luke had died, and had been buried in Achaia, which Gregory Nazianzen says, was the province assigned to St. Luke. Lardner.

LUKE's Gospel, St., in *Biblical History*, the gospel written by the evangelist Luke. That the gospel and the Acts were written by St. Luke, is a fact that is confirmed by the testimony of the most unexceptionable of ancient writers. To this purpose we may observe, that this gospel is often cited by Justin Martyr, who lived A.D. 140, and by the martyrs of Lyons, A.D. 177. Irenæus, A.D. 178, says expressly, that Luke, the companion of Paul, put down in a book the gospel preached by him. Clement of Alexandria, A.D. 194, has borne ample testimony to this gospel, as well as the Acts. Tertullian, A.D. 200, asserts against Marcion the genuineness and integrity of the copies of St. Luke's gospel, owned by himself and Christians in general, and for this he appeals to divers apostolical churches. Luke's digest, says this ancient father, is often ascribed to Paul; it being easy to take that for the master's which the disciples published. Origen, A.D. 230, mentions the gospels according to the order in which they are now generally received; and "the third," he says, "is that according to Luke, the gospel commended by Paul, published for the sake of the Gentile converts." Eusebius of Cæsarea, A.D. 315, speaking of St. Paul's fellow-labourers, says, "and Luke, who was of Antioch, and by profession a physician, for the most part a companion of Paul, who had likewise a more than slight acquaintance with the rest of the apostles, has left us in two books, divinely inspired, evidence of the art of healing souls, which he had learned from them. One of these is the gospel, which he professed to have written, as they delivered it to him, 'who from the beginning were eye-witnesses and ministers of the word,' with all whom he says likewise, he has been perfectly acquainted from the very first. The other is the Acts of the Apostles, which he composed now, 'not from what he had received by the report of others, but from what he had seen with his own eyes.'" In the Synopsis, ascribed to Athanasius, but supposed to be written about the end of the fifth century, it is said, "that the gospel of Luke was dictated by the apostle Paul, and written and published by the blessed apostle and physician Luke." But it is needless in this place to cite a greater number of authorities.

As to the time in which this gospel was written, it may be settled without much difficulty. The Acts of the apostles were published A.D. 63 or 64, and not long after the gospel, as is generally allowed. Accordingly Dr. Mill supposes, those books to have been two parts of one and the same volume, and to have been published in the year of Christ 64. The gospel itself bears internal characters of the time in which it was written. As to the place where it was written, learned writers have differed. Jerom says, that Luke, the third evangelist, published his gospel in the countries of Achaia and Beotia. Gregory Nazianzen also says, that Luke wrote for the Greeks, or in Achaia. Grotius says, that about the time when Paul left Rome, Luke departed to Achaia, and there wrote his books, which we have. Cave thought that they were written at Rome, and before the termination of Paul's captivity. But it is said by Mill, Grabe, and Wetstein, that Luke published his gospel at Alexandria in Egypt. Dr. Lardner has particularly examined these different opinions; and he concludes, that "upon the whole, there appears not any good reason to say, that St. Luke wrote his gospel at Alexandria, or that he preached at all in Egypt. It is more probable, that when he left Paul, he went into Greece, and there composed, or finished, and published his gospel, and the Acts of the apostles." Origen was of opinion that this gospel was written for gentile converts; Jerom says, that of all the evangelists Luke was best skilled in the Greek language, and that he wrote his gospel more especially for gentiles, but Chrysostom maintains that he wrote for all in general. Luke himself, at the beginning of his gospel, assigns the reason of his writing, declaring, that whereas many others had rashly undertaken to give a relation of the matters which he most surely believed, he thought himself obliged, in order the better to divert us from the uncertain relations of others, to deliver in his gospel a certain account of those things, which he was well assured of from his intimate acquaintance and familiarity with Paul, and his conversation with the other apostles. So says Eusebius.

St. Luke has inscribed his two books, his gospel, and the Acts to Theophilus, by whom some understand any good Christian in general, others a particular person. Augustin, Chrysostom, and many others, have understood Theophilus to be a real person. Cave supposed him to be a nobleman of Antioch; but it seems more probable, that if St. Luke published his books in Greece, as we have already stated, Theophilus, to whom they are addressed, was a man of the same country. It is of greater importance to ascertain, who are designated by the many mentioned by the evangelist, who before him had attempted to write histories of Jesus Christ. Epiphanius supposes, that St. Luke here refers to Cerinthus, Merinthus, and others of that description. Origen and Jerom say, that many attempted to write gospels, as Basilides, Apelles, and others; and they mention several such, not received by the church; such as the gospel of Thomas and Mathias, the gospel of the Egyptians and of the Twelve. Theophylact seems to imagine, that the evangelist referred to the two later gospels now named. Grabe, while he allows that St. Luke did not refer to the gospels of Basilides or Thomas, or some others mentioned by Origen, for they were not published till after St. Luke's death, thinks, that St. Luke might refer to the gospels according to the Egyptians, and according to the twelve, and some others. But against this opinion it might be urged, that the gospel according to the Egyptians was not composed before the second century. Dr. Mill is of opinion, that of the many narrations to which St. Luke refers, the two principal were the gospels according to the Hebrews,

Hebrews, and according to the Egyptians. About the year 58, or somewhat sooner, says Mill, were composed, by some of the faithful, evangelical narrations, or short histories of Christ. The writers were not our evangelists Matthew and Mark; but some of the first Christians, who, before Luke, and also before Matthew and Mark, wrote histories of the things done by Christ, and received from apostolical tradition, not with a bad or heretical design, but with the same design with our evangelists; but their histories, as we may infer from St. Luke's account, were inaccurate and imperfect, and they contained some things not certain, or well attested, and possibly some mistakes. Dr. Lardner, who upon the whole approves the preceding statement, cannot allow the gospel according to the twelve, or according to the Hebrews, to have been one of the memoirs or narrations; to which St. Luke refers; for these were short histories, whereas that was a full gospel, supposed to have been either St. Matthew's original Hebrew gospel with additions, or his original Greek gospel, translated into Hebrew with additions. Moreover, the gospel according to the Egyptians could not have been one of these memoirs, because it was an heretical gospel, probably composed in the second century by some Encratites, who were enemies of marriage. Whatever the memoirs or narrations were, none of them now remain, nor even so much as any fragments, nor quotations of them occurring in any Christian writings now extant. Marcion, a heretic who lived in the first half of the second century, rejected all the gospels, except that of St. Luke, and this he mutilated and altered, and interpolated in a great variety of places. He would not allow it to be called the gospel of St. Luke, erasing the name of that evangelist from the beginning of his copy. Some of his followers considered it as written partly by Christ himself, and partly by the apostle Paul. Marcion retrenched the first and second chapters entirely, and begun his gospel at the first verse of the third chapter, and even read this in a manner different from our copies, viz. In the 15th year of Tiberius Cæsar, God descended into Capernaum, a city of Galilee. Some late Christian writers have concurred in Marcion's retrenchment; but without sufficient authority. Lardner.

St. Luke, says a modern writer, is pure, copious, and flowing in his language, and has a wonderful and entertaining variety of select circumstances in his narration of our Saviour's divine actions. He acquaints us with numerous passages of the evangelical history, not related by any other evangelist: both in this gospel and Apostolical Acts, he is accurate and neat, clear and flowing, with a natural and easy grace; his style is admirably accommodated to the design of history; it had a very considerable resemblance to that of his great master St. Paul; and, like him, he had a learned and liberal education, and appears to have been very conversant with the best classics; for many of his words and expressions are exactly parallel to theirs. Blackwall's Sacred Classics.

LUKE'S DAY, *St.*, is a festival observed on the 18th of October.

LUKE'S HOSPITAL, *St.* See HOSPITAL.

LUKE'S KEYS, in *Geography*, two small islands near the coast of Honduras. N. lat. 15° 50'. W. long. 86° 35'.

LUKOMLA, a town of Russia, in the government of Polotsk; 60 miles S.S.E. of Polotsk.

LUKOW, a town of Poland, in the palatinate of Lublin; 40 miles N. of Lublin.

LUKOWA, a town of Poland, in the palatinate of Belez; 44 miles W.S.W. of Belez.

LUKOWO, a town of Lithuania, in the palatinate of Brzeze; 80 miles E. of Pultk.

LULANIS, in *Botany*, a name given by some of the ancient Greeks to a plant, used very frequently for a yellow colour in dyeing, and by the ladies for tinging their hair yellow, the favourite colour of those times. Neophytus explaining this word, says, that it signified the same with isatis, glastum, or woad; and several others have been of that opinion, though very absurdly, since the glastum or woad dies a blue colour, not a yellow; and by no means answers the description of the lulanis, which is the same with the lutum, or lutea herba of the Romans, and with the genifella tinctoria, or dyers'-weed of these times.

LULEA, or LULA, in *Geography*, a sea-port of Sweden, in West Bothnia, on the N. side of the river Lulea, at the N.W. extremity of the gulf of Bothnia, with a good harbour; 68 miles W. of Tornea. N. lat. 65° 38'. E. long. 22° 4'.

LULES, LOS, a town of South America, in the province of Tucuman; 50 miles N. of St. Miguel de Tucuman.

LULLI, JOHN BAPTIST DE, in *Biography*, secretary to Louis XIV., and superintendant of his music, was born at Florence in 1633, having a miller for his fire. A Cordelier gave him his first lessons in music upon the guitar, though he afterwards applied to the violin. He was only thirteen when the Chevalier de Guise, being on his travels in Italy, proposed to his parents to take him into France, and engage Mademoiselle de Guise, his sister, to take him among the officers of her kitchen.

This princess having accidentally heard him play on the violin, had him taught, and he became in a short time an excellent performer.

Louis XIV. being desirous to hear him, was so pleased with his performance, that in 1652, he appointed him inspector-general of his violins, and soon after created a new band, which was called *les petits violons*. These new musicians formed by Lulli soon became the first in Europe, which is not saying much for them, as such was the ignorance of the generality of instrumental performers at this time, that they could execute nothing which they did not know by heart.

The genius, therefore, of Lulli was obliged to contract itself to the abilities of his orchestra, and it is supposed that he would have written as well as his successors, if he had lived a hundred years later.

Before the establishment of the opera in France, the king every year gave to his court magnificent spectacles called *ballets*, in which there was a great number of symphonies, mixed with recitatives. Lulli first began by only composing the music to the dances in these ballets; but the king became so fond of his compositions, that he would hear no other.

In 1672, Perrin, to whom the patent for an opera was first granted, resigned it to Lulli, whose genius began to expand, and he may be regarded as the creator of this kind of music, which (according to M. Laborde) has not been so much improved (in France, he should have said) as some imagine, and in many particulars has, perhaps, lost more than it has gained.

It is true, that he was assisted by the immortal Quinault,

of whom he had the penetration to discover the genius, and the dexterity to secure the assistance by a deed, in which the poet engaged to supply him every year with a new drama, for 4000 livres, about 200*l*.

Quinault sketched many plans, and carried them to the king for his approbation: after which Lulli pointed out to him the places where the dances were to be introduced, and let him hear the airs. The scenes were examined, by his majesty's command, in the Académie des Belles Lettres. Thus by their united opinions, all the dramas of Quinault were regulated, which remain the best that were produced in France during the 17th century, and will probably continue the best, if new set, for many ages yet to come. The enemies of Quinault, jealous of his glory and talents, contrived to bring about a quarrel between the poet and musician. Lulli had recourse to La Fontaine, who, at his request, produced the opera of "Daphne," but as soon as Lulli had heard it read, he did not conceal from the author, that he thought his talents did not extend to writing operas. La Fontaine, piqued at having laboured in vain, to revenge himself on Lulli, for his coarse rejection of his drama, wrote his comedy, or rather satire, of "The Florentine," but as he had a good heart, he soon subdued his wrath, and they were sincerely reconciled.

The king, more and more pleased with his music, conferred on him the title and emoluments of secretary to his majesty, and heaped upon him many other favours for his family.

The king having been extremely ill in 1686, Lulli composed a Te Deum on his recovery, which was executed in the church of the Feuillans, Rue Saint Honoré, the eighth of January 1687. In enthusiastically regulating the time with his cane, he struck his foot so violently, that, probably from a bad habit of body, a mortification came on. He was at first advised to have the toe taken off which was wounded by the cane, then the foot, and then the leg. But some quacks having promised to cure him without amputation, Messrs. de Vendôme, who had a sincere regard for him, offered to the quacks 2000 piñoles if they cured him, and lodged them in the hands of a banker. But all their efforts were useless, and it was announced to him that he must prepare for death. His confessor refused to give him absolution, but upon condition that he would burn the opera of Achilles and Polixene, which he had been preparing for the stage. He consented, and the composition was committed to the flames.

Some days after, fancying himself a little better as the gangrene encreased, one of the young princes of Vendôme came to see him; "What! Baptist, (says he,) hast thou been so foolish as to burn such good music?"—"Hush! hush! my lord, (whispers Lulli,) I have got a copy of it." However, it is asserted, that he manifested in his last moments a sincere repentance, and testified the highest sense of religion. He died at Paris on the 22d of March 1687, in the 54th year of his age. He was buried in the church of Les petits Pères, in La Place des Victoires, where a fine monument was erected to his memory, and where may have been read, before the revolution, the following epitaph by Santeuil:

"Perfida mors, i. linica audax, temeraria et excors,
Crudelique, et cœca probris te absolvimus illis,
Non de te querimur, tua sint hæc munia magna.
Sed quando per te populi Regisque voluptas,
Non ante auditis rapuit qui cantibus orbem
LULLIUS eripitur, querimur modo, furdus fustli."

Lulli was a fortunate man to arrive in a country where music had been so little cultivated, that he never had any

rival, nor was there throughout the whole kingdom of France an individual who had the courage to doubt of his infallibility in his art. He was fortunate in so magnificient a patron, and still more fortunate in a Lyric poet, who could interest an audience by all the powers of poetry, by the contexture of his fables, and variety and force of his characters.

Lulli was rough, rude, and coarse in his manners, but without malice. His greatest frailties were the love of wine and money. There were found in his coffer 630,000 livres in gold, an exorbitant sum for the time in which he lived. He had the art of making himself at once beloved and feared by the performers of his music, which is doubtless the most essential talent for governing such eccentric and mutinous subjects; but however difficult it may be to keep them in order and in good humour, true merit, exact justice, and a steady conduct always succeed.

Lulli married the only daughter of Michel Lambert, the celebrated musician, and the best singing-master of his time. By this marriage he had three sons and three daughters, to all of whom he left an ample provision, and friend in power, who conferred on them places, pensions, and kindred.

LULLY, RAYMOND, a philosopher and chemist of great note in the dark ages, was born in the island of Majorca in 1236, of an illustrious family of that name at Barcelona. From the works that bear his name, it is supposed that he was ardently attached to the study of the sciences, of philosophy, theology, chemistry, and medicine; but there is great doubt as to the genuineness of many of those works, which were probably written by his pupils, or even by persons who lived considerably posterior to his time. In his youth he bore arms, and led the life of a man of pleasure. It is related of him that he fell in love with a young damsel, named Eleonora, who obstinately rejected his addresses; and at length, when he was one day strongly pressing his suit, and demanding the reason of her refusal, she exposed her breast consumed with a cancerous ulcer. This spectacle is said to have inspired him with a resolution of seeking a remedy for her disease, and to have been the motive which led him to the chemical studies, for which he became celebrated, as well as to a journey into Africa, for the purpose of consulting the works of Geber. But others affirm that the sight had such an effect upon him, that he plunged into religious retirement, and devoted the rest of his days to pious purposes. It appears certain that he undertook a course of travels into Africa and the East, with the view of converting the Mahometans to the Christian faith, where he incurred greath hardships and dangers, and whence he was permitted to depart only upon condition of not returning. He was still, however, so much inflamed with zeal for this object, that he entered the Franciscan order, and again visited Africa. When he was again found there, he was thrown into prison, and after suffering much torture, was released through the intercession of some Genoese merchants, who took him on board their ship; but he died on the passage when just in sight of his native land, in 1315. Others assert that he was stoned to death while preaching to the infidels in Africa, on the 26th of March of that year.

From this narrative, which represents Lully in the light of a fanatic missionary, we should not expect that scientific character which has caused his name to be preserved to modern times. It seems, however, that he had travelled in England, France, and Germany; and he calls himself a disciple of Roger Bacon, whom he had probably seen in his journey. As a chemist, indeed, he appears in an extraordinary light; for although he is believed to have been a

first who mentioned the philosopher's stone, and though that was the leading object of his researches, together with the fancied *panacea*, or universal remedy; yet he maintained that chemistry was only to be acquired, and these objects to be obtained by a series of experiments; and that the art was not to be taught by words. Boerhaave says of the chemical works extant in Lully's name, that he has perused most of them, and finds them beyond all expectation excellent; so that he has been tempted to doubt whether they could be the work of that age. "So full," says he, "are they of the experiments and observations which occur in later writers, that either they must be supposititious, or the ancient chemists must have been acquainted with many things which pass for modern discoveries."

Lully has also been celebrated as a scholastic metaphysician. He introduced into the schools a "new transcendent art," which was distinguished by his name, and by means of which a person might hold a disputation for a whole day, upon any subject whatever, without understanding any thing of the matter. This invention suited the genius of the age. It consisted in collecting a number of general terms, common to all the sciences, of which an alphabetical table was to be provided. Subjects and predicates taken from these were to be respectively inscribed in angular spaces upon circular papers. The essences, qualities, affections, and relations of things being thus mechanically brought together, the circular papers of subjects were fixed in a frame, and those of predicates were to be placed upon them as to move freely, and in their revolutions to produce various combinations of subjects and predicates, whence would arise definitions, axioms, and propositions, varying infinitely. This contrivance, worthy of Laputa, was greatly admired in its time, and its author acquired the title of *the most enlightened despot*.

The following are the titles of those of his works which relate to chemistry: "De Secretis Naturæ, seu de Quinta Essentia, Libellus," first printed in 1518, 4to. and frequently republished; "Apertorium de veri Lapidis compositione," 1546; "Testamentum duobus Libris universam Artem Chemicam complectens. Item ejusdem Compendium animæ transmutationis Artis metallorum," 1566; "Liber Mercuriorum;" "De Arte brevis;" "Secreta Secretorum;" "Codicillus, seu Vade Mecum, in quo fontes Alchymicæ Artis et Philosophicæ reconditoris uberrimè traduntur." Many manuscript essays of Lully are preserved in the library at Leyden, and upwards of a hundred, it is said, which have never been published, in that of Venice. A complete edition of all the writings attributed to this author was published at Mayence in 1714, including treatises on theology, morals, medicine, chemistry, physics, law, &c. Gen. Biog. Eloy Dict. Hist.

LULLY'S ART. See ART, and the preceding article.

LULOLA, in *Geography*, a strong town in Angola, situated on an island about 100 miles from the mouth of the Cuanza, fortified by the Portuguese.

LULWORTH, EAST, a parish in the hundred of Wimborne, in Blandford division of Dorsetshire, England, is situated six miles from Wareham, and 116 from London, and contains 74 houses and 364 inhabitants. The chief object worthy of notice here is Lulworth castle, the seat of — Weld, esq. It is situated in the south-east corner of an extensive park, which occupies a circuit of nearly four miles and a half, and has been lately surrounded by an excellent stone wall, upwards of eight feet high. The present edifice, which was built on or near the site of a castle mentioned so far back as the year 1146, was commenced in 1588, and finished in 1609, except the internal decorations,

which were not completed till after the year 1641, when the ancestor of the late owner purchased the estate. The castle is an exact cube of eighty feet, with a round tower at each corner thirty feet in diameter, and rising sixteen feet above the walls, which, as well as the towers, are embattled. The hall and dining-room are spacious, and the rooms in general eighteen feet high. The principal front is on the east, and is faced with Chalkmark stone, decorated with statuary. In the year 1789, during their majesties' residence at Weymouth, Mr. Weld had several royal visits, the particulars of which are recorded in two inscriptions over the entrance to the castle. Mr. Weld has lately erected an elegant little chapel for the convenience of his family; this structure is of a circular form, increased by four sections of a circle, so as to form a cross, and finished with a dome and lantern. The parish church of St. Andrew (which was an ancient and curious fabric) has been recently rebuilt at the expense of Mr. Weld.

United with the foregoing parish, and about a mile distant towards the sea, is that of West Lulworth, which contains 73 houses and 312 inhabitants. At a small distance is Lulworth Cove, a sort of natural basin, into which the sea flows through a wide gap in the cliff, sufficient for the entrance of vessels of 70 or 80 tons burthen. About a mile from the cove is the Arched Rock, which projects from the land into the sea, having an opening near 20 feet high in the middle, formed like an arch, through which the prospect of the sea has a peculiar effect. Beauties of England and Wales, vol. iv.

LUMACHELLE MARBLE. See MARBLE.

LUMAMPA, in *Geography*, a town of South America, in the province of Tucuman; 90 miles S. of St. Yago del Estero.

LUMBAGO, in *Medicine*, signifies a pain in the loins (*lumbi*), especially from rheumatism, affecting the ligaments of the spine, or the muscles of the back. See RHEUMATISM.

The only diseases which are liable to be mistaken for *lumbago* in general, are painful affections of the kidneys, which, it is well known, are seated within the lumbar region on each side of the spine; especially inflammation of these glands, or the formation of calculi in them, or the passage of these concretions through the ureters towards the bladder. The symptoms, attendant upon these disorders of the kidneys, will be found described in their proper places. (See NEURALGIA, NEPHRITIS, and GRAVEL.) We may observe here, that, in *lumbago*, the pain does not follow the course of the ureters, it is not accompanied with retraction of the testicle in men, it is not increased by external pressure, it is often little felt, except in the erect posture, and there is no vomiting, nor any change in the quantity or quality of the urine; the contrary of all which is observed in inflammatory and calculous affections of the kidneys.

The internal remedies, commonly administered for the cure of other forms of rheumatism, are also beneficial in the *lumbago*; such as opiates, with antimonials and other sudorifics, taken at bed-time, and followed by laxatives in the morning, or combined with laxatives, especially the submuriate of mercury, preparations of sulphur, or salts. Much relief, however, is afforded by the application of local stimulants to the lumbar region externally. Liniments of camphor, turpentine, and similar substances, have been found from the experiments of Dr. Hume, Dr. Ferriar, and others, among the most efficacious of these applications. Dr. Ferriar affirms, that he has found a solution of camphor in sulphuric ether relieve the pains of diseased joints, after all other

applications had failed; and he relates several cases in which a liniment, resembling that proposed by Dr. Home, proved an effectual cure for lumbago. He used two drams of camphor, an ounce of balsum, and half an ounce of black soap, anattig the oil of turpentine, ammonia, and seed of cymum, prescribed by Dr. Home. The effect of this application, he says, is commonly the removal of the pain within three days, often in a much shorter time. See Ferriar. Med. Hist. and Reflect. vol. i. p. 188. Home, Clin. Exper. p. 261, § xiv.

LUMBALIS, in *Anatomy*, an epithet applied to some parts placed about the loins. The lumbar arteries are branches of the aorta, and the lumbar veins terminate in the inferior vena cava. (See ARTERY and VEIN.) The lumbar nerves are five pairs proceeding from the medulla spinalis. (See NERVE.) The lumbar muscles are the *psoæ*; which see. For an account of the lumbar vertebrae, see SPINE. The lumbar region of the abdomen is the lateral and posterior part of the umbilical region, the part, in short, which constitutes the loins in common language. See ABDOMEN.

LUMBAR, in *Geography*, a town of Spain, in Navarre; 15 miles N. of Sangüeta.

LUMBAR Abscess, in *Surgery*. See *Psoas Abscess*.

LUMBERTON, in *Geography*, a post-town of America, in North Carolina, and capital of Robeson county, on Drowning creek; 32 miles S. of Fayetteville; it has a court-house, and about 36 dwelling-houses.

LUMBI, in *Anatomy*. See *LOINS*.

LUMBO, in *Geography*, a town of Benguela; 120 miles E. N. E. of Benguela. S. lat. $11^{\circ} 45'$.

LUMBORUM QUADRATUS, in *Anatomy*, *ileo-costien* of Dumas, a muscle situated towards the side and lower part of the vertebral column, and extending from the crista of the os innominatum, and the ileo-lumbar ligament, to the lower edge of the last false rib, and to the transverse processes of the four first vertebrae of the loins. It has the form of an elongated square, but is rather broader below than above. Its anterior surface is covered above by the diaphragm, then by the anterior lamina of the aponeurosis of the transversus abdominis, and towards the inside by the psoas. It corresponds to the kidney and to the colon. Its posterior surface is covered by the middle aponeurosis of the transversus, which separates it from the common mass of the sacro-lumbalis and longissimus dorsi. The outer edge is inclined a little from above downwards, and from within outwards, and corresponds to the angle formed by the separation of the anterior posterior laminae of the aponeurosis of the transversus abdominis. The inner margin is attached to the points of the transverse processes of the four first lumbar vertebrae by as many flattened pieces. The lower edge is attached to the middle of the posterior part of the crista ili, for an extent of about two inches; it is also fixed to the ileo-lumbar ligament. The upper edge is inserted in the lower margin of the last false rib, for a more or less considerable extent in different subjects; in some it occupies nearly the whole length, in others only the inner third part.

It is fixed to the crista of the os innominatum by aponeuroses, which ascend to a considerable height on the anterior surface and the outer edge. These fibres, which proceed from below upwards, are crossed below by others, which arise from the transverse process of the last lumbar vertebra. The fleshy fibres ascend rather obliquely from without inwards, and the internal are the shortest; they terminate at the transverse processes of the lumbar vertebrae by tendinous fibres. The external and longer ones end at the lower edge of the last false rib by short aponeuroses. Sometimes an-

other muscular stratum arise from the front of the transverse processes of the third and fourth lumbar vertebra, pass obliquely outwards, and is blended with the rest of the muscle.

The quadratus lumborum inclines the loins towards its own side; when these are fixed, it may raise the pelvis on that side, and lower it on the opposite. By drawing downwards the last false rib, it may be concerned in respiration.

LUMBRE, in *Geography*, a town of France, in the department of the Straits of Calvès, and chief place of a canton, in the district of St. Omer. The place contains 502, and the canton 13,655 inhabitants, on a territory of 262½ kilometres, in 36 communes.

LUMBRERAS, a town of Spain, in Leon; 22 miles N. N. W. of Ciudad Rodrigo.

LUMBRICALES, in *Anatomy*, certain small muscles of the fingers and toes, connected with the flexor tendons of those organs. See FLEXOR.

LUMBRICOIDES. See ASCARIS.

LUMBRICUS, EARTH-WORM, in *Natural History*, a genus of the vermes-intestina class and order. Body round, annulate, with generally an elevated fleshy belt near the head, mostly rough, with minute concealed prickles placed longitudinally, and furnished with a lateral aperture. There are sixteen species contained in this genus, of which four are natives of this country.

Species.

* **TERRESTRIS**; Common earth-worm, sometimes named dew-worm. Body red, with eight rows of prickles. There is another variety exactly like this, only half the size. The body contains about one hundred and forty rings, each of which has four pair of prickles, not visible to the naked eye, but discoverable to the touch: when expanded, it is convex on each side; but when contracted, it is flattish beneath, with a red canal down the body; the belt is wrinkled and porous; mouth placed beneath the proboscis. It inhabits decayed wood and common soil, which, by perforating, it renders fit to receive the rain; it devours the cotyledons of plants, and wanders about by night; it is the food of moles, hedge hogs, and various birds.

This worm has neither bones, brains, eyes, nor feet. It has a number of breathing holes situated along the back, and near each ring. The heart is placed near the head, and may be observed to beat with a very distinct motion. The small rings are furnished with a set of muscles, that enable it to act in a sort of spiral direction; and by this means it is capable, in the most complete manner, of creeping on the earth, or penetrating into its substance. These muscles enable the worm to contract or dilate its body with great force. The rings are each armed with small stiff sharp prickles, which the animal is able to open out or close upon its body; and from beneath the skin there is secreted a slimy matter, which, by lubricating the body, greatly facilitates its passage through the earth.

This worm has been confounded with the *ASCARIS Lumbricoides*, or round worm of the human intestines; which see. The difference between the two may be briefly pointed out in this place.

The common earth-worm has its extremities much blunter than those of the intestinal; its mouth consists of a small longitudinal fissure, situated on the under surface of a small rounded head, there being no appearance of the three vesicles which are found in the ascaris. On the under-surface of the earth-worm there is a large semi-lunar fold of skin, into which the head retreats: but this is wanting in the ascaris. The anus of the earth-worm opens at the very ex-

cremity of the tail, and not, as in the ascaris, at a considerable distance from it. The ascaris wants the transverse rugae, which are so strongly marked in the earth-worm, as well as the broad yellowish band by which the body of the latter is surrounded.

The internal structure of the two worms is also extremely different. In the earth-worm there is a complete and large stomach, consisting of two cavities; and the intestinal canal in the latter is larger, and more formed into sacculi than in the ascaris. The parts subservient to generation in these worms are very different: in the ascaris there is a distinction of sex, but the common earth-worm is hermaphrodite.

Dew-worms, though a small, and frequently regarded as a despicable link in the chain of nature, would, if lost, be greatly missed by those who are apt to consider them as a nuisance. For, independently of their affording a large supply of food to birds, &c. already noticed, they are of great use in promoting vegetation, by boring, perforating, and loosening the soil, and rendering it pervious to rain and the fibres of plants, by drawing straws and stalks of leaves and twigs into it; and, most of all, by throwing up such numbers of lumps called worm-casts, which act as a fine manure for grain and grass.

* **MARINUS.** Lug. Back with two rows of bristly tubercles; body pale red, round, and annulate, with greater or less rings; the first prominent, with two opposite tufts of short bristles on each, the lower part smooth. It is found on the shores of England, and other parts of the European coast, where it buries itself in the sand to a great depth, leaving a little rising with an aperture on the surface. It is used as a bait for fishes.

VERMICULARIS. Body white, with two rows of prickles. It inhabits the wet and decayed trunks of trees, and among moist leaves, moving very expeditiously in moist places, but twisting itself up in dry ones. Its body is polished and glabrous.

VARIEGATUS. Rufous spotted, with six rows of prickles. It inhabits wet plantations, and is the most beautiful of the whole genus. The body red, very finely tessellate with brown, having a sanguineous line running down the whole body. It easily breaks in pieces, and as easily reproduces what has been lost by accident or otherwise.

TUBIFEX. Body reddish, with two rows of prickles; the body is pellucid, very simple, thin, and truncate at the tip, with a dark intestine. It is found at the bottom of rivulets, where it forms a perpendicular tube of earth for its habitation.

LINEATUS. Body white, with a longitudinal red line. Found very abundantly on the shores of the Baltic, among sea-weed. It is pellucid, with rather a short body, having a yellow artery on the back, and a bifid vein towards the head.

CILIATUS. Body rufous, and ciliate between the rings; the body is glabrous, with about forty segments; the intersections are armed with four tufts of short bristles.

TUBICOLA. White, with a red dorsal spot on each of the segments. This species is found in the bays of Norway that have a clayey bottom, in a round membranaceous tube, covered with mud, and about an inch longer than itself. It has twenty-five segments in the body, of which the intersections are armed with two bristles on each side; the intestine is black, and running down the whole body.

ECHINURUS. Body covered with rows of granulations; the hind-part obtusely truncate, and surrounded with a double crown of bristles. It inhabits the sandy bottom of the shores of Belgium; is most observable in winter, and is the chief food of cod-fish. Body whitish-grey, with fulvous

viscera, about the size of a person's middle finger; tongue fleshy, thickish, and boat-shaped.

* **THALASSEMA.** Body striate, dirty red, with shining red spots, beneath grey; mouth surrounded with a funnel-like tube, which is wrinkled within, and plaited at the margin; the body is glabrous, mucous, thicker at one end, and somewhat pointed at the other; the mouth is placed above, with a saffron funnel. Inhabits the shores of Cornwall.

EDULIS. Body whitish-flesh-colour, subclavate behind, dilated and papillose before; mouth terminal, and surrounded with a villous rim or wrinkle. There are two hundred and seventy-eight rings between the villous part and the hinder end, separated by an annular stria; the hind-part bulbous, with a double papilla; the fore-part beset with numerous flesh-coloured ones disposed in transverse rows.

* **OXYURUS.** Body whitish-livid, very sharp at the hind extremity, and obtuse before, with a round, retractile, and exsertile proboscis. This species is found on the Suller coast, is about an inch and a half long, and annulate with very fine striae; snout truncate, and very fine, granulate, with a pore at the base scarcely visible.

FRAGILIS. Body red, with lateral divided warts, and fasciculate bristles. The body of this species resembles the terrestris, with above five hundred smooth and very brittle rings; the head is conic, with an approximate wrinkled mouth. It inhabits the muddy bottom of the bays of Norway.

ARMIGER. Body red, with double lanceolate lamellæ on the belly, and none on the fore-part; is about two inches long, and consisting of about two hundred rings. Found in the islands of Norway.

CIRRATUS. Body armed with very long cirri. Inhabits the Norway seas.

SABELLARI. Body jointed, and truncate at one end; the intersections of the joints thick, and armed with two prickles. It resembles the tubicola, and is found in the Norwegian seas.

LUMELLA, in the *Glass-trade*, the round hole in the floor of the tower of the leer, which is directly over the working surface, and by which the flame is let into the tower.

LUMELLO, in *Geography*, a town of Italy, in the department of the Gogna. This place lately gave name to a district in the duchy of Milan, called "Lumalline," on the Gogna; once the residence of the kings of Lombardy, now a village; 26 miles S.W. of Milan. N. lat. 48 57'. E. long. 8 47'.

LUMHAGAN, an island in the straits of Malacca, near the coast of Salengora, 12 miles long, and 5 broad; separated from the continent by a narrow channel, called the "Straits of Lumhagan." N. lat. 2 54'. E. long. 101 24'.

LUMJOCKI, a town of Sweden, in East Bothnia; 12 miles S.W. of Ulea.

LUMINOSA SEMITA. See SEMITA.

LUMINOUS COLUMN, and *Fire.* See the substantives.

LUMINOUS Emanations, have been observed from human bodies, as also from those of brutes. The light arising from currying a horse, or from rubbing a cat's back, are known to most. Instances of a like kind have been known on combing a woman's head. Bartholin gives us an account, which he entitles "mulier splendens," of a lady in Italy, whose body would shine, whenever slightly touched with a piece of linen. These effluvia of animal bodies have many properties in common with those produced in glass; such as their being lucid, their snapping, and their not being excited

cited without some degree of friction; and are undoubtedly electrical, as a cat's back has been found strongly electrical when stroked. See **ELECTRICITY** and **LIGHT**.

Human bodies not only appear luminous, but even the exhalations from them adhering to their clothing will cause it to shine likewise.

LUMINOUSNESS of the Sea. See **LIGHT** and **SEA**.

LUMIO, in *Geography*, a town in the island of Corsica; 5 miles N.E. of Calva.

LUMME, in *Ornithology*. See **COLYMBUS Trile**.

LUMO, in *Geography*, a town of the island of Cuba; 45 miles S.S.W. of Havannah.

LUMP-FISH, in *Ichthyology*. See **CYCLOPTERUS Lumpus**.

LUMP of Fish, in the *Mange*. See **BOUILLON**.

LUMPARAN, in *Geography*, an island of Sweden, east of Aland, between the Baltic and the gulf of Bothnia. N. lat. 60° 7'. E. long. 20° 3'.

LUMPEN, in *Ichthyology*, the name of a fish, common in the markets at Antwerp, of a long and round body, growing gradually slenderer to the tail. Its colour is a greenish-yellow, with black broad lines on the back, placed transversely; and it has a little redness at the end of its tail.

The lumpen is a species of the blenni, distinguished by Artedi by the name of the *blennius*, with fins like cirri under its neck, and transverse streaks on the back. The cirri are biid.

LUNPOKOLSKOL, *Niznei*, in *Geography*, a town of Russia, in the government of Tobolsk, on the Oby. N. lat. 61°. E. long. 76° 54'.

LUNPOKOLSKOL, *Torchnei*, a town of Russia, in the government of Tobolsk. N. lat. 60° 54'. E. long. 78° 22'.

LUNPS, in *Rural Economy*, a term made use of to signify barn-floor bricks, in some places.

LUNA, in *Astronomy*. See **MOON**.

LUNA, in *Ancient Geography*, *Lunegiano*, a town situated on the Maera, which had a port in Liguria, called "Luna Portus," which, according to Strabo, was a very large and fine harbour, containing several others. The town was situated to the west of the mouth of the river Maera, and was afterwards called "Cariaram," both names alike signifying Luna, the moon, and referring to its form, which was that of a crescent. Lucan speaks of its aruspices; Servius and Martial of its cheese, marble, and wine. According to Strabo, it was destroyed by Nero; and some of its ruins are still visible in a place called Lunigona, and its small territory is named Lunegiano. M. Gebelin conjectures that the name Luna was derived from the Celtic *lun*, water.

LUNA, in *Geography*, a town of Spain, in Arragon; 22 miles W. of Huesca.—Also, a town of Lithuania, in the palatinate of Troki; 16 miles S.E. of Grodno.

LUNA CORNEA, in *Chemistry*, is the combination of marine acid with silver, or the white curdy precipitate of muriat of silver, which takes place, when the nitrat, acetat, or any other soluble salt of silver comes in contact with muriatic acid, either single or in any soluble combination. See **SILVER**.

To make this combination, the silver is first dissolved in nitrous acid; to this solution marine acid, or more usually common salt dissolved in water, is added. The mixture soon becomes turbid, and a copious precipitate is formed in it, which has always the appearance of curd. The solution of salt is added, till no more precipitate is formed. The precipitate, when separated from the liquor that swims over

it, is called luna cornea; because if this matter be exposed alone to fire, the acid carries off with it a portion of the silver, and the remaining matter melts, assuming the form of a horny substance.

The best method of reducing luna cornea, or of separating silver from marine acid, according to Margraaf, is to digest half an ounce of fine silver in aqua regia, to precipitate it by a sea-salt, and edulcorate the precipitate, which will then weigh five drams sixteen grains. For the reduction of this precipitate, mix it with an ounce and a half of dry volatile sal ammoniac, triturate them well together with a little water during a quarter of an hour; then add three ounces of mercury obtained from cinabar by means of quick-lime, and continue to triturate during some hours with a little more water. Thus an amalgam will be formed, which being washed from a white powder and dried, will weigh three ounces and half a dram. By distillation of this amalgam, a residuum of silver, four grains less than the original half ounce, will be obtained. By subliming the white powder, which weighs five drams, three grains of silver will be obtained; but if the amalgam and white powder be distilled together, the operation will fail, and the luna cornea be recomposed. (Berlin Mem. 1749.) M. Beaucourt says, that luna cornea may be reduced without loss by fusion with four times its weight of fixed alkali.

Luna cornea mixed with sea-salt and tartar rubbed on brass gives a silver-like appearance; and is the substance employed for the silvering of the dial-plates for clocks. A more substantial silvering may be given by the above mixture, if the piece of brass to be silvered be previously heated considerably, and cleaned with a scratch brush; and if the operation be repeated, till the silver seems to be sufficiently thick. The brass having a stronger disposition to unite with the marine acid than the silver has, separates this acid from the silver, which is then precipitated upon the surface of the brass plate. The luna cornea will also serve in examination of mineral waters, or of any other liquor, to dissolve if they contain marine acid in whatever base it be engaged, except metallic bases; for if these waters contain the smallest quantity of marine acid, a luna cornea will be precipitated by them from a solution of silver in nitrous acid, and this luna cornea is known by its acid-like appearance. Macquer, Chem. Dict. Engl. edit.

LUNAR *Horoscope*. See HOROSCOPE.

LUNAR *Month*. See MONTH.

LUNAR *Observations*, or *Lunar Method*, is the method of finding the longitude, by taking the distance between the moon and the sun, or a fixed star, which has been already explained under the article LONGITUDE; but the great importance of this problem induces us here to give a further and more minute explanation of its principles and operations, and of the different methods that have been devised for obtaining the solution.

This method of finding the longitude is the greatest modern improvement in navigation: the idea, however, is not modern, but it has not been applied with any success until within the last fifty years. M. de la Lande mentions certain astronomers who, above two hundred years ago, proposed this method, and contended for the honour of the discovery; but its present state of improved and universal practice he very justly ascribes to Dr Maskelyne. The discovery, indeed, seems to claim less honour than its subsequent improvements; it is one of those things which are obvious in theory, but difficult in practice. The most ancient method of finding the longitude was by the lunar eclipses; and that of finding it by the lunar distances is perfectly analogous: it is therefore highly probable that the method was thought of at a very early period, but the want of proper tables and apparatus prevented its being reduced to practice.

It may be observed, that, in the most practical methods of finding the longitude at sea by celestial observations, the moon is the chief guide or instrument; for the quickness of her motion renders her peculiarly well adapted for measuring small portions of correspondent time. Now, as she is seen in the same part of the heavens nearly at the same instant of absolute time, from all parts of the earth where she is visible, and as she is continually and sensibly changing her place, it is evident that if two correspondent observers were to note the precise moment of the respective times, when she is seen in any particular part of the heavens, *the difference between these times would shew the difference of longitude.*

In every method of finding the longitude by the moon, the first object is to be able to ascertain the part of the heavens where she is: this is easily seen at the time of her eclipses, or at the occultation of a fixed star; and these were naturally the first methods resorted to, but they occur too seldom for general use: the moon's place, however, may be marked with equal precision, by taking her distance from some fixed object, whose latitude and longitude are known; and stars in or near the zodiac are preferred, as the nearer such objects are to the moon's orbit, the greater will be her motion with respect to them: and though her motion is not uniform, yet, during the short space of time that she is near any star, she may be considered as moving uniformly.

It has been above observed, that if two persons under different meridians were to mark the moon's place, and also their relative times of observation, they might thence tell their difference of longitude; but they could not communicate their observations sufficiently soon for practical purposes; and even admitting the possibility of this, it were

necessary that the longitude of one place should be known, in order to determine that of the other. Now the Nautical Almanac is calculated to supply all these wants. This admirable work may be considered a perpetual observer, that communicates universally and instantaneously certain celestial appearances, as they take place at Greenwich Observatory. Here the distances are given between the moon and the sun, and certain remarkable stars in or near the zodiac, for every three hours; and any intermediate distance, or time, may be thence found by the rule of proportion with sufficient accuracy. If, therefore, under any meridian, a lunar distance be observed, *the difference between the time of observation and the time in the Almanac, when the same distance was to take place at Greenwich, will shew the longitude.* For example, if the observed distance between the sun and moon be 50° at eight o'clock, but by the Almanac the same distance of 50° will take place at Greenwich at six, it is evident that the difference between the observed and computed time is two hours, and therefore the longitude is 30° ; and it is also clear that the longitude is east, the time being most advanced at the place of observation.

A method so apparently simple must have been long since adopted; but two difficulties occurred: one the want of proper instruments, which want has been happily supplied by the invention and subsequent improvement of Hadley's quadrant; and the other, correct lunar tables; for the moon, though so near and so conspicuous to the earth, has always perplexed astronomers more than any other celestial body. The various inequalities of her motions were never properly understood, until sir Isaac Newton discovered the physical laws which govern them; and from his theory professor Mayer formed lunar tables, which have been found sufficiently correct for nautical practice, and from which those tables in the Nautical Almanac of the lunar distances had been calculated under the direction of Dr. Maskelyne for many years. In 1806 the French board of longitude published new lunar tables, calculated by Du Burgh, from the theory of La Place and the observations of Dr. Maskelyne; and from these tables the lunar distances in the Nautical Almanac of 1813 are computed, and in the Almanacs that follow.

The above two difficulties having been obviated, a third seems still to remain; and though this is in some measure removed by the application of the Nautical Almanac and Requisite Tables, yet the calculation is still more tedious than might be wished; nor is it possible to render it much shorter, as the problem necessarily comprehends solutions in two spherical triangles: this arises from the circumstance of the *observed distances* between the heavenly bodies not being the *true distances*; for the altitudes of those bodies are more or less affected both by refraction and parallax; and though these effects only operate in a vertical direction, yet that which changes the altitude of two bodies must also change their distance asunder. This is evident from the consideration, that the altitude of a celestial object is an arc of an azimuth circle intercepted between the object and the horizon; and as all azimuth circles incline gradually to each other from the horizon to the zenith, where they meet, it is plain that the more two bodies are apparently raised, the less will be their apparent distance asunder, and the contrary.

It is well known that the heavenly bodies are raised by refraction, and depressed by parallax; and that these effects are greatest in the horizon, and gradually diminish to the zenith, where they become nothing. Refraction depends upon altitude alone, but parallax depends upon both altitude and

LUNAR OBSERVATIONS.

and distance. All celestial objects, except the moon, are more affected by refraction than by parallax, and therefore appear above their true places; but the moon is always seen, excepting in the zenith, below her true place, being more affected by parallax than refraction, on account of her proximity to the earth.

These effects of parallax and refraction, though counteracting each other, seldom do it so equally as to render all correction unnecessary. Sometimes the *apparent* distance is nearly a whole degree more or less than the *true* distance; and the principal cause of so great a difference is the moon's parallax: for this body, which is the chief guide to the longitude, is also the great cause of error in the distances, and is therefore the principal object of correction.

In making a lunar observation, four persons are generally employed, one of whom takes the distance, two the altitudes, and the fourth notes the time. These things should be performed at the same instant; and if the observation be repeated several times, and a mean taken, the work is likely to be the more correct; and great care is here necessary, for an error in this part of the operation, particularly in taking the distance, will pervade the subsequent parts of the work, and will of course produce a wrong solution. The manner of adjusting the instruments, and of making the observations, is best taught by practice. Those who wish for written instructions on the subject are referred to the British Mariner's Guide by Dr. Maskelyne, to Dr. Mackay's book upon the longitude, or to professor Vince's Practical Astronomy.

Of correcting the Altitudes of the observed Objects.—When a lunar observation is made, the first object is to clear the altitudes from semidiameter, dip, refraction, and parallax.

The moon's parallax in altitude must be next calculated; by saying, *As radius is to the sine of her zenith distance, so is the sine of her horizontal parallax (as given in the Nautical Almanac) to the sine of her parallax in altitude.*

In correcting the moon's altitude, an allowance should be made for the augmentation of her semidiameter, which gradually takes place from the horizon to the zenith. This increase is given, in the IVth of the Requisite Tables, for every five degrees of altitude, which correction is to be added to her horizontal semidiameter given in the Nautical Almanac.

The augmentation of the moon's semidiameter is caused by her being nearer to the spectator in the zenith than in the horizon by a semidiameter of the earth—for the magnitude of a body is in the inverse ratio of its distance from the observer; and as the earth's semidiameter bears a very sensible proportion to the moon's distance, she is seen under the greatest angle in the zenith, which angle gradually diminishes to the horizon.

There are other corrections of the altitudes which may be necessary in cases of particular nicety, but which are seldom noticed at sea. These are—an allowance for the contraction of the vertical semidiameters of the sun and moon by refraction; a correction of the moon's parallax, supposing the earth an oblate spheroid; a correction for the refraction, according to the actual state of the atmosphere, as shewn by a thermometer and barometer, and not according to the mean astronomical refraction which is commonly used. These corrections, though perhaps necessary towards the perfection of this problem, being very small, and frequently counteracting each other, are generally considered of little consequence in nautical practice, where greater errors are unavoidable.

From the corrected Altitudes to find the true Distance.—It is easy to conceive, that by a lunar observation, the three sides

of a spheric triangle are measured in the heavens, which sides are the apparent co-altitudes of the observed bodies, and their apparent distance asunder.

The co-altitudes or zenith distances being corrected, the question is, to find the true distance between the observed bodies; but here there are only two things given, and therefore it cannot be performed until the angle at the zenith is known, which is determined from the three given sides of the triangle, by the rules of spheric trigonometry.

As the effects of parallax, refraction, &c. operate only in a vertical direction, it is evident that the corrections of the zenith distances or containing sides will not change the included angle at the zenith; and therefore three things are now known, namely, the corrected zenith distances and the included angle, whence the other side is determined by spherics, and this side is the true distance sought.

A General View of the different Methods of working the Lunar Observations.—Few problems have been ever more investigated or studied than that of clearing the lunar distance, and many ingenious methods have been devised for contracting the operation. These methods are founded on some of the following general principles.

The first general principle is spheric trigonometry, as before explained; the second is the doctrine of proportional errors, by which the effects that the errors in the altitudes produce on the distance are solved by fluxions, or by the *differential calculus*: and a third principle has been lately discovered, which is founded on the properties of a quadrangle inscribed in a circle, as explained and exemplified by the inventor, Dr. Andrew, in his Astronomical and Nautical Tables.

Various methods of working the lunar observations have been devised chiefly by Halley, Euler, Mayer, Maskelyne, Lyons, Witchell, Burrow, Borda, Wales, Mackay, Kelly, Gerrard, Andrew, and Mendoza. The methods of the two last authors appear the most concise, but all are sufficiently correct, and seamen generally prefer such as they have first learnt. It may indeed be observed, that operations which appear the most concise are not always the most expeditiously performed, as much depends on the number and variety of tables required, and the manner of applying them. No method has hitherto obtained an exclusive preference over the rest, nor does it appear possible to reduce the calculation to a conciseness to answer the general purposes or wishes of seamen; and hence, other modes have been devised, of obtaining approximate solutions by projection or graphic operation.

The first graphic method for clearing the distances was that by La Caille, called the *Chassis de reduction*, which has since been copied by La Lande, Mackay, and others. It is an orthographic projection, consisting of a great number of lines accurately drawn, and various scales for obtaining the different corrections.

Another graphic operation, of a different description, was executed by the late George Margetts, and published in 1790. It consists of seventy large plates, containing numerous lines drawn from the solutions of lunar distances in Dr. Shepherd's Tables. By Margetts' Longitude Tables the solution of a lunar observation may be obtained in about one-fourth of the time required by calculation; and the answer, though not perfectly accurate, is sufficiently correct for the general purposes of navigation.

An orthographic projection, founded on the fluxional analogies of spheric triangles, has been devised by Dr. Kelly, and published in his Introduction to Spherics and Nautical Astronomy, where an investigation of its principles is given (p. 195, edit. 2 and 3.) with a demonstration,

stration, shewing, that in all proper altitudes it will give the true distance within a few seconds. The simplicity of this projection is extremely curious, as giving an approximate solution of a complicated problem, by drawing four right lines only from the scale of chords, and it must therefore be very useful where great expedition is required.

LUNAR Rainbow. See RAINBOW.

LUNAR Year. consists of three hundred and fifty-four days, or twelve synodical months. See YEAR.

In the first ages, the year used by all nations was lunar; the variety of course being more frequent in this planet, and of consequence more conspicuous, and better known to men than those of any other. The Romans regulated their year, in part, by the moon, even till the time of Julius Cæsar; the Jews too had their lunar months. Some rabbins pretend, that the lunar month did not commence till the moment the moon began to appear; and that there was a law, which obliged the person who discovered her first, to go and inform the sanhedrim thereof. Upon which the president solemnly pronounced the month begun, and notice was given of it to the people by fires lighted on the tops of mountains. But this appears somewhat chimerical.

LUNARE Os, in *Anatomy*, one of the bones of the carpus. See EXTREMITIES.

LUNARIA, in *Botany*, elegantly so named by the older botanists and by all succeeding ones, from *luna*, the moon; on account of the silvery semi-transparent aspect, and broad orbicular shape, of its seed-vessels. Honefly or Sattin-flower. Linn. Gen. 337. Schreb. 440. Willd. Sp. Pl. v. 3. 476. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 2. 385. Juss. 239. Tourn. t. 105. Lamarek Illustr. t. 561. Gærtner. t. 142, *rediviva*.—Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliquosæ*, Linn. *Crucifera*, Juss.

Gen. Ch. Cal. Perianth inferior, oblong, of four ovate-oblong, obtuse, cohering, deciduous leaves, of which two opposite ones are gibbous and pouched at the base. Cor. cruciform, of four equal, large, undivided, obtuse petals, as long as the calyx, each tapering down into a claw of the same length. Stam. Filaments fix, awl-shaped, about the length of the calyx, two of them rather shorter; anthers erect, or slightly spreading. Pist. Germen stalked, ovate-oblong, compressed; style short, permanent; stigma obtuse, undivided. Peric. Pouch elliptical, compressed quite flat, undivided, erect, very large, stalked, terminated by the style, of two cells and two valves; the partition flat, parallel and equal to the valves. Seeds several, projecting into the middle of the pouch, kidney-shaped, compressed, bordered, supported by long thread-shaped stalks, inserted into the lateral sutures.

Eff. Ch. Pouch undivided, elliptical, flat, stalked; valves equal and parallel to the dissepiment, flat. Calyx-leaves bagged at the base.

1. *L. rediviva*. Perennial Honefly. Linn. Sp. Pl. 911. (*L. græca perennis*; Bell. Eyst. vern. ord. 1. t. 21. f. 1. *Viola lunaris*, longioribus siliquis; Ger. em. 464. f. 2.)—Leaves doubly and sharply toothed. Pouches elliptic-lanceolate, acute at each end.—Native of Germany, Switzerland, and Greece. In our gardens it flowers in May or June, and is perennial, but by no means common. The stems are three or four feet high, erect, round, leafy. Leaves on long stalks, heart-shaped, pointed, nearly smooth, doubly, sharply and finely toothed; the lower ones opposite, the rest alternate. Flowers numerous, large, corymbose, fragrant, crimson. Pouch two inches long and not one broad, elliptical, making a sharp angle at each extremity, green or brownish.

2. *L. annua*. Annual Honefly. Linn. Sp. Pl. 911.

Mill. Illustr. t. 54. (*Viola lunaris*, five *Bolbonac*; Ger. em. 464. f. 1.)—Leaves simply and bluntly toothed. Pouch elliptical, somewhat orbicular, rounded at each end.—Native of Germany and Switzerland; very common in gardens, flowering in May and June. The root is annual or rather biennial, tapering. Stem solitary, branched. Leaves with much broader and less taper teeth than in the former, in a simple series only. Flowers copious, large, scentless, crimson. Pouch glaucous, scarcely more than an inch long, and nearly as broad, being almost orbicular, rounded at each end.

Linæus having founded his specific differences of these plants on the opposite or alternate situation of their leaves, in which respect they both vary, has led some to suppose they were both the same. Nothing however can be more distinct than the shape of their seed-vessels, to which we have added the different manner in which their leaves are toothed. They also permanently differ as to duration.

Willdenow charges Gærtner wrongfully with figuring the pouch of *L. rediviva* for *Ricotia*; the latter differs in not being elevated on a stalk above the base of the flower, which stalk in the said *Lunaria* is an inch long, or more. *Ricotia* is observed by Mr. R. Brown, as well as by Gærtner, to have, sometimes at least, two cells.

L. annua was discovered wild in Switzerland by M. Schleicher, though Haller seems not to have been aware of it.

LUNARIA, in *Gardening*, comprises plants of the herbaceous, annual, and perennial kinds, of which the species cultivated are, the perennial honefly (*L. rediviva*); the annual honefly, moor-wort, or satin-flower (*L. annua*); and the Egyptian honefly (*L. Egyptiaca*).

In the second sort the seed-vessels, when fully ripe, become transparent, and of a clear shining white, like satin; whence the name of satin flower.

Method of Culture.—These plants may be raised by sowing the seed in a shady border, or, which is better, in patches in the situations where they are to remain, in the autumn, keeping the plants afterwards properly thinned out and free from weeds. They may likewise be sown in the early spring; but the former is the better season, as the plants rise stronger. The last sort should have an open situation. When sown in beds, the perennial sort should be set out where they are to remain, in the following autumn after being sown.

These plants all afford ornament and variety in the borders and clumps of pleasure-grounds, in which the first sort should be placed more backward.

LUNARIA, in *Ichthyology*, a species of *Perca*; which see.

LUNARIA, in *Natural History*, is also used by some authors for the scelerites.

LUNARIS COCHLEA, the name of a genus of shells of the snail-kind, according to the classification of some writers, the distinguishing character of which is their having a perfectly round mouth. These are univalve, unbilobed shells, with a depressed clavicle, and a surface sometimes smooth, but more frequently striated, furrowed, lacinated, or covered with tubercles.

It is said, that Archimedes took the invention of the screw, so famous ever since his time, and still called after his name, from the form of this shell; and it is generally allowed, that architects have taken the hint of their winding flights of stairs from it. See TROCHUS, HELIX, &c. under CONCHOLOGY.

LUNAS, in *Geography*, a town of France, in the department of the Hérault, and chief place of a canton, in the district of Lodève. The place contains 1296, and the canton

canton 6122 inhabitants, on a territory of 292 $\frac{1}{2}$ kilometres, in 12 communes.

LUNATI, CARLO AMEROSIO, in *Biography*, of Milan, furnished *Il Gobbo della Regina*, who came to England in the reign of James II. Lunati was a most celebrated performer on the violin, and Geminiani's first master on that instrument.

LUNATIC, LUNATICUS, a person supposed to be affected, or governed by the moon. Hence, epileptics were anciently called lunatici, because the paroxysms of that disease seemed to be regulated by the changes of the moon. Thus Galen, (*De Diebus Criticis*, lib. iii.) says, the moon governs the periods of epileptic cases: and others referred the disease entirely to this planet. *Retæus de Diuturnis Morbis*, lib. i. cap. 4. See Mead's *Treatise concerning the Influence of the Sun and Moon upon the Human Bodies*, p. 38. 46, &c.

Mad people are still called lunatics, from an ancient but now almost exploded opinion, that they are much influenced by that planet. A much sounder philosophy hath taught us, that if there be any thing in it, it must be accounted for, not in the manner the ancients imagined, nor otherwise than what the moon has in common with other heavenly bodies, occasioning various alterations in the gravity of our atmosphere, and thereby affecting human bodies. However, there is considerable reason to doubt the fact; and it is certain that the moon has no perceivable influence on our most accurate barometers.

A lunatic, in the contemplation of the law, is properly a person who hath lucid intervals; sometimes enjoying his senses, and sometimes not. See NON-COMPOS.

The stat. 17 Edw. II. cap. 10. ordains, that the king is to provide that the lands of lunatics be safely kept, and they and their families maintained by the profits, and the residue shall be kept for their use, and be delivered to them when they come to their right mind; the king taking nothing to his own use; and if the parties die in such state, the residue shall go to their executors or administrators. A warrant is now issued by the king, under his royal sign manual, to the lord chancellor, or lord keeper, or lords commissioners for the custody of the great seal, to perform this office for him. All matters, therefore, touching lunatics, are within the peculiar jurisdiction of the court of chancery.

Lunatics are not legally accountable for any crimes they commit in this state. (1 Hawk. c. 1.) And also, if a man in his sound memory commits a capital offence, and before arraignment for it he becomes non-compos, he ought not to be arraigned for it; and if, after he has pleaded, the prisoner becomes mad, he shall not be tried: if, after he be tried and found guilty, he loses his senses before judgment, judgment shall not be pronounced: and if, after judgment, he becomes of non-sane memory, execution shall be stayed.

By the common law, if it be doubtful whether a criminal, who at his trial is in appearance a lunatic, be such in truth or not, it shall be tried by an inquest of office, to be returned by the sheriff; and if it be found by them, that the party only feigns himself mad, and he still refuse to answer, he shall be dealt with as if he had confessed the indictment. 1 Hawk. c. 1. §. 4.

By 39 and 40 Geo. III. c. 94.; in all cases, where it shall be given in evidence upon the trial of any person for treason, murder, or felony, that such person was insane at the time when the offence was committed, and such person shall be acquitted, the jury shall be required to find specially, whether they acquitted him on

account of insanity; and if they do so find, the court shall order such person to be kept in strict custody in such place, and in such manner as to them shall seem fit, until his majesty's pleasure shall be known; whereupon his majesty may give such order for the safe custody of such person during his pleasure in such place and manner as to his majesty shall seem fit.

When any person, who shall be indicted for any offence, and upon arraignment shall be found by the jury to be insane, so that he cannot be tried, or when upon the trial he shall be found to be insane, the court may record such finding, and order the party to be kept in strict custody until his majesty's pleasure shall be known; and if any person, charged with any offence, shall be brought before any court to be discharged for want of prosecution, and such person shall appear to be insane, the court may order a jury to be impanelled to try the sanity of such person; and if the jury find him to be insane, the court may order such person to be kept in strict custody, &c.; and in all cases of insanity his majesty may give such order, &c. as stated above.

And for the better prevention of crimes being committed by persons insane, if any person shall be discovered and apprehended under circumstances that denote a derangement of mind, and a purpose of committing some crime, for which if committed he would be liable to be indicted, any justice, before whom such person shall be brought, may, if he think fit, issue a warrant for committing such person as dangerous, and suspected to be insane, such cause of commitment being plainly expressed in the warrant; the person so committed shall not be bailed, except by two justices, one whereof shall be the justice who issued such warrant; or by the quarter sessions; or by one of the judges.

By 17 Geo. II. c. 5. it is enacted, that whereas there are sometimes persons, who by lunacy or otherwise are furiously mad, or are so far disordered in their senses, that they may be dangerous to be permitted to go abroad, it shall therefore be lawful for two or more justices, where such lunatic or mad person shall be found, by warrant directed to the constables, churchwardens, and overseers of the place, or some of them, to cause such person to be apprehended, and kept safely locked up in some secure place within the county or precinct, as such justices shall under their hands and seals direct and appoint, and (if such justices find it necessary) to be there chained, if the settlement of such person shall be within such county or precinct.

And if such settlement shall not be there, then such person shall be sent to his settlement by a vagrant pass (*mutatis mutandis*); and shall be locked up or chained by warrant of two justices of the county or precinct to which such person is so sent in manner aforesaid.

And the reasonable charges of removing, and of keeping, maintaining, and curing such persons, during such restraint (which shall be during such time only as such lunacy or madness shall continue) shall be satisfied and paid (such charges being first proved upon oath) by order of two justices, directing the churchwardens or overseers, where any goods, chattels, lands, or tenements of such person shall be, to seize and sell so much of the goods and chattels, or receive so much of the annual rents of the lands as is necessary to pay the same; and to account for what is so seized, sold, or received, to the next quarter sessions; but if such person hath not an estate to satisfy the same, over and above what shall be sufficient to maintain his family, then such charges shall be paid by the parish, town, or place to which such person belongs, by order of two justices, directed to the churchwardens or overseers for that purpose.

Provided, that any person aggrieved by any act of

such justices out of sessions may appeal to the next sessions, giving reasonable notice; whose order therein shall be final.

And nothing herein shall restrain or abridge the power of the king or lord chancellor; nor shall restrain or prevent any friend from taking them under their own care and protection.

But the above parts of the act relate to vagrant lunatics only, who are strolling up and down the country, and do not extend to persons, who are of rank and condition in the world, and whose relations can take care of them properly by applying to the court of chancery. 2 Atk. Rep. 52. See MADHOUSES.

When a person is legally found to be *non-compos*, (see NON-COMPOS,) the lord chancellor usually commits the care of his person, with a suitable allowance for his maintenance, to some friend, who is then called his *committee*, which see. However, to prevent sinister practices, the next heir is seldom permitted to be this committee of the person; because it is his interest that the party should die. But it hath been said, there lies not the same objection against his next of kin, provided he be not his heir; for it is his interest to preserve the lunatic's life, in order to increase the personal estate by savings, which her or his family may be hereafter entitled to enjoy. (2 P. Wms. 638.) The heir is generally made the manager, or committee of the estate, it being clearly his interest by good management to keep it in condition; accountable, however, to the court of chancery, and to the *non-compos* himself, if he recovers; or otherwise, to his administrators. In this care of idiots and lunatics, the civil law agrees with ours; by assigning them tutors to protect their persons, and curators to manage their estates. But in another instance the Roman law goes much beyond the English. For, if a man by notorious prodigality was in danger of wasting his estate, he was looked upon as *non-compos*, and committed to the care of curators or tutors by the praetor. And by the laws of Solon such prodigals were branded with perpetual infamy. But with us, when a man on an inquest of idiocy hath been returned an *unthrif*t and not an *idiot*, (which see,) no further proceedings have been had. Bro. Abr. tit. Idiot 4.

By 29 Geo. II. c. 31, a lunatic may surrender a lease in the court of chancery or exchequer, in order to renew the same. Also, by direction of the lord chancellor, he may accept a surrender of such lease, and execute a new one. 11 Geo. III. c. 20.

By 43 Geo. III. c. 75. whereas great injury frequently happens to persons found lunatic or of unsound mind, and incapable of managing their affairs, and the creditors of such persons are delayed in obtaining payment of their demands for want of sufficient power to apply the property of such persons in discharge of their debts and engagements, it is enacted that it shall be lawful for the lord chancellor, lord keeper, or lords commissioners for the custody of the great seal, to order the freehold and leasehold estates of such persons respectively to be sold, or charged by way of mortgage or otherwise, for raising such sum of money as shall be necessary for payment of the debts, and for performing the contracts or engagements of any such persons respectively, and [of] the costs and charges attending the same, and attending such sale or incumbrance respectively, and to direct the committee or committees of the estate of such persons respectively to execute in the name and on behalf of such persons conveyances of the estates to be sold or incumbered, and to procure such admittance to and make such surrenders of the copyhold estates of such persons found lunatic or of unsound mind, and to do all

such acts as shall be necessary to effectuate the same in such manner, as such chancellor, &c. shall direct; which conveyances shall be as good in law, as if the same had been executed by every such person when in his or her sound mind.

And in case of any surplus of money to be raised by any such sale as aforesaid, after answering the purposes aforesaid, the same shall be applied in the same manner as the estate sold would have been applied, if this act had not been made.

And whereas many such persons may be seized and possessed of freehold and copyhold lands, &c. either for the term of their natural lives or for some other estate, with power of granting leases and taking fines, reserving small rents on such leases for one, two, or three lives, in possession or reversion, or for some number of years determinable upon lives, or for terms of years absolutely; be it enacted, that in every such case every power of leasing such lands, &c. which is or shall be vested in such person, having a limited estate only, shall and may be executed by the committee or committees of the estate of such person, under the direction and order of the lord chancellor, lord keeper, or lords commissioners; and such lease or leases shall be as good in law, as if the same were executed by the said person in his or her sound mind.

And whereas persons so found lunatic or of unsound mind may be seized or possessed of, and entitled to freehold or copyhold estates, in fee or in tail, and an absolute interest in leasehold estates, and it may be for their benefit that leases or under leases should be made of such estates for terms of years, and especially to encourage the erection of buildings thereon, or repairing buildings actually being thereon, or otherwise improving the same; be it enacted, that it shall be lawful for the lord chancellor, &c. to order and direct a committee or committees of the estate of such lunatic to make such leases of the freehold, copyhold, or leasehold estates of such persons respectively, according to his or her interest therein, and to the nature of the tenures of such estates, for such term or terms of years, and subject to such rents and covenants, as the lord chancellor, &c. shall direct; and that every such lease shall be as good in the law, as if the same had been executed by such persons in his or her sound mind.

Every act to be done by such committee or committees by virtue of this act, and the order of the lord chancellor, &c. shall be as valid and binding against the said persons so found lunatic and of unsound mind respectively, and all persons claiming by, through, or under him or her respectively, as if the persons so found lunatic or of unsound mind respectively had been in his or her sound mind, and had personally done such act or acts respectively.

Provided nevertheless, that nothing herein shall extend to subject any part of the freehold, copyhold, or leasehold estates of any person found lunatic or of unsound mind, to the demands of his creditors, otherwise than as the same are now subject by due course of law; but only to authorise the lord chancellor, lord keeper, or lords commissioners for the custody of the great seal of the united kingdom and of Ireland respectively, being intrusted by virtue of the king's sign manual with the care and commitment of the custody of the persons, and estates of persons so found lunatic or of unsound mind, to make order in such cases as are hereinbefore mentioned, when the same shall be deemed for the benefit of such person so found lunatic or of unsound mind, and incapable of managing his or her affairs.

To make a will, it is not sufficient that the testator have memory to answer to familiar and usual questions, but

he ought to have a disposing memory, so as to be able to make a disposition of his estate, with understanding and reason.

For the marriage of lunatics, see *MARRIAGE*.

For lunatic asylums, see *MAD-HOUSES*.

LUNATION, the period, or space of time, between one new moon and another; also called *synodical month*. See *CYCLE* and *EPACT*.

LUNAWARA, in *Geography*, a town of Hindoostan, in Guzerat; 50 miles E. of Amedabad.

LUND, a town of Sweden, in West Gothland, on the Wenner lake; 36 miles N.N.E. of Uddevalla.

LUND, or *Lunden*, the most ancient town of Sweden, the capital of Scania, Schonen, or Skonen, of which a proverb is recorded, *viz.* that when our Saviour was born, Lund was in its glory. Lund contains scarcely more than 800 inhabitants, carries on but little trade, and is principally supported by the university established by Charles XI., and called, from the name of its founder, "Academia Carolina Gothorum." When Mr. Coxe visited Sweden, it had 21 professors and 300 students. The library contains 20,000 volumes. The botanical garden was not in a flourishing state, the number of plants not exceeding 1200. Linnæus was matriculated at this university. (See *LINNÆUS*.) At Lund was instituted, in 1776, a Royal Physiographical Society, which was incorporated by the king in 1778. The subjects treated of in its acts relate only to natural history, chemistry, and agriculture. Lund is an archbishopric. The cathedral is an ancient irregular building, raised at different intervals; 21 miles E. of Copenhagen. N. lat. 55° 44'. E. long. 13°.

LUNDA, a town of Sweden, in Sudermanland; 10 miles W. of Nyköping.

LUNDBY, a town of Norway, in the province of Agderhus, on the Glomme; 60 miles N.E. of Christiania.

LUNDE, a town of Norway, on a lake of the same name; 28 miles W.N.W. of Christianland.—Also, a town of Norway; 17 miles N.W. of Skeen.

LUNDEN, a town of the duchy of Holstein; 24 miles W. of Rendsborg.

LUNDO, a town of Sweden, in the government of Abo; 8 miles N.E. of Abo.

LUNDRESS, in our *Old Writers*, a sterling silver penny; which had its name from being coined only in London, and not at the country mints.

LUNDSAY, in *Geography*, a town of Pegu, on the W. side of the river Ava; 60 miles W.N.W. of Pegu. N. lat. 18° 30'. E. long. 95° 43'.

LUNDSJE, a town of Persia, in the province of Laristan, on the Persian gulf. N. lat. 26° 38'. E. long. 54° 36'.

LUNDSKORON, a town of Poland; 18 miles S. of Cracow.

LUNDY ISLAND, is situated in the mouth of the Bristol channel, nearly four leagues from the coast of Devonshire, England. It is rather more than three miles in length, and about one in breadth; contains about 2000 acres; and is environed by high and steep rocks, which render it inaccessible, except in one or two places. The only safe landing place is on the east side; where a small beach admits a secure approach, and is sheltered by a detached portion of rock, called the Isle of Rats, from the great number of those animals which burrow here. On landing, visitors are obliged to climb over various craggy masses, before they can reach the steep and winding tract that leads to the summit, which commands views of the English and Welsh coasts. About 400 acres only of this

island are in cultivation; of which 300 are arable, and the rest pasture: wheat is the chief produce. The elevated situation of the land, in some places 800 feet above the sea, and the violence of the N.E. winds, prevent any tree from growing, though a considerable expense has been incurred in planting. Rabbits and rock birds are numerous; and in the season, lobsters, crabs, and other fish may be obtained in abundance. About 400 head of sheep, and 80 of cattle, are fed here; but the former do not thrive. The inclosures are stone fences. Of the history of the island but little is known. Riddon relates that one Morisco, who had conspired to kill king Henry III., retired hither, and turning pirate, committed great depredations; on which the king arrested, and had him executed on an elevated part. About the middle of the last century, it was purchased of government by a nobleman, who entrusted it to the care of a person named Benson, a notorious smuggler, who carried on a considerable illicit traffic. The next proprietor of the island was sir John Borlase Warren, who, about the year 1781, sold it to John Cleveland, esq.; but it appears to have been recently re-purchased by government. The whole rent is but 70*l.* per annum; no taxes are paid; nor can it maintain any revenue officer, the duties in seven years scarcely amounting to five pounds. The number of houses is only seven; the inhabitants, in the year 1794, were but twenty-three. The population of the isle was probably greater at some distant period, as many human bones have been ploughed up; and Camden says, "the turrows show it to have been once cultivated." The chief antiquities are, the ruins of St. Anne's chapel, and what is termed Morisco's castle. The latter is near the south-east end, and was strongly fortified with large out-works and a ditch; a few old dismounted cannon occupy the battlement, beneath which is a curious cavern. In the reign of Charles I. lord Say and Seale held the castle for the king; and in the time of William and Mary, the French surprised it by a stratagem, plundered it, and kept possession for some time. Beauties of England and Wales, vol. iv.

LUNE, in *Fortification*. See *DEMI-LUNE* and *LUNETTE*.

LUNE, or *Lugne*, in *Geography*, a river of England, which rises in the county of York, and runs into the Irish sea, a few miles below Lancaster. N. lat. 53° 57'. W. long. 2° 49'.

LUNE, **LUNULA**, in *Geometry*, is the space included between the arcs of two unequal circles, forming a sort of crescent, or half-moon, the area of which may in many cases be as accurately determined as that of any rectilinear figure. The lune was the first curvilinear space of which the quadrature was ascertained, and this is said to have been first effected by Hippocrates of Chios, though others say it was discovered by Ctenopidas of Chios. However this may be, the former geometer has generally had the honour of the discovery attributed to him, and the figure still bears his name, being commonly denominated the lune of Hippocrates, the construction of which is as follows.

On the diameter of a semicircle (*Plate X. Geometry, fig. 2.*) describe a right-angled triangle, of which the angular point will necessarily fall in the circumference. Then on each of the sides *A D*, *D B*, describe a semicircle, and the two figures *A G F D*, *D H E B* will be lunes, and the area of them will be equal to the area of the right-angled triangle *A D B*. For circles, and consequently semicircles, being to each other as the squares of their diameters; and since $A B^2 = A D^2 + D B^2$; therefore the semicircle $A D B = A G D + D H B$; from these equal spaces taking away the common segments *A F D* and *D E B*, there remain the two lunes equal to the triangle *A D B*; and therefore, if the

two sides AD , DB , become equal, as in *fig. 3*, the two lunes are each equal to half that triangle, and consequently the quadrature of them is determined, being each equal to a given rectilinear figure; and this is what is properly called the lune of Hippocrates, and it was the only one of which he could determine the area, for though he, in all cases, had the measure of the space of both together, yet it was only in the case of equality that he could find the area of the single lune, though he could always determine a lune that should be equal to any given rectilinear space. For in *fig. 3*, the arc DEB is a quarter of a circle to the radius CB , and DHB is a semicircle. If, therefore, we construct the isosceles right-angled triangle BCA , (*fig. 3*.) equal to any given space, and on AB describe the semicircle BDA , and from C as a centre, and with CA as a radius, describe the quadrant BEA , we shall have the lune $BDEA$ equal to the given space as required. This, as we have observed above, was the first instance of the quadrature of a curvilinear space, that is, of its being shewn equal to a rectilinear figure; for, properly speaking, it is not absolutely a quadrature, as was that of Archimedes, when he demonstrated that every parabola was two-thirds of its circumscribing rectangle; Hippocrates arriving at his result only step by step, by subtracting equal quantities from equal spaces, and hence finally, as by chance, coming to a case in which a curvilinear area is equal to a rectilinear one.

This discovery of Hippocrates, it seems, inspired him with great confidence of being able to find the measure of the circle itself; and the reasoning which has been attributed to him on this subject, though very erroneous, is still extremely plausible. Hippocrates supposed a semicircle $ADEB$ (*fig. 4*.) in which he drew the three chords or radii AD , DE , EB , and on each of these chords he described a semicircle and a fourth, as F , equal to them. Then the four semicircles AGD , DEH , EIB , and F , being each equal to a quarter of the semicircle $ADEB$, they are therefore together equal to it, and taking away from each the small segments AGD , DHE , EIB , we shall have on one side the rectilinear figure $ADEB$, equal to the three lunes, together with the semicircle F . If, therefore, the area of the lunes be taken away from the rectilinear $ADEB$, there will remain the area of the semicircle F , equal to a given rectilinear space. This reasoning, however, though ingenious, is still very defective, in consequence of the lunes employed in this case being different from those of which Hippocrates had found the quadrature, for that, as we have seen, is bounded by a quadrant of one circle, and the half of another, whereas those in the above figure are bounded by a semicircle, and the sixth part of another circle, which is very different from the former, and the quadrature of it equally as difficult as that of the circle itself. All, therefore, that Hippocrates could draw from his investigation, was merely this, that if any geometer should be able to find the area of those lunes, the quadrature of the circle would necessarily follow, and as this problem was not at that time thought so difficult as it is now known to be, it is not improbable that considerable hopes of success were entertained after the discovery which this able geometer had made of the possibility of squaring what is indeed apparently a more complex figure than the circle. In fact the quadrature of the circle might be accomplished, if we only knew the ratio of the two lunes, described as in *fig. 2*; for then knowing the sum of the two, and their ratio, it is obvious that we should have the real area of each, and consequently, by taking AD equal to the radius BC , the area of the circle would follow, as we have shewn above.

But though Hippocrates and the ancient geometers were

unable to square any other lune, except that above-mentioned, yet the moderns have found several other cases in which the quadrature may be obtained, as also certain portions of them cut off by right lines, drawn in certain directions. In the lune of Hippocrates, the radii of the bounding circles are to each other in the ratio of two to one; but if the two circles are to each other as three to one, or as three to two, or as five to one, or five to three, they may also be squared, or may be constructed equal to given spaces, by means of the simple elements of geometry; but other ratios, as four to one, six to one, seven to one, &c. require the assistance of the higher geometry, being of a similar description of problems to those of trisecting an angle, doubling a cube, &c.; and can only be solved by the same means.

We shall take this opportunity of giving a summary of some of the most curious observations, added by modern geometers to the discovery of Hippocrates.

1. If from the centre F , (*fig. 5*.) there be drawn any straight line whatever FE , cutting off the portion of the lune $AEGA$, that portion will be quadrable, and equal to the rectilinear triangle AHE . For it may be readily demonstrated, that the segment AE will be equal to the semi-segment AGH .

2. From the point E , if EI be let fall perpendicularly on AC , and FI and EF be drawn, the same portion of the lune $AEGA$ will be equal to the triangle AFI . For it may be easily demonstrated, that the triangle AFI is equal to the triangle AHE .

3. The lune, therefore, may be divided in a given ratio, by a line drawn from the centre F ; nothing more being necessary than to divide the diameter AC in such a manner, that AI shall be to CI in that ratio; to raise EI perpendicular to AC , and to draw the line EF : then the two segments of the lune AGE and GEC will be in the ratio of AI to CI .

All these remarks were first made by M. Artus de Lionne, bishop of Gap, who published them in a work, entitled "Curvilinearum Amoenitas Contemplatio," 1654. 4to., and afterwards the following were added by other geometers.

4. If two circles, forming the lune of Hippocrates, be completed, the result will be another lune, which may be called the *conjugate* to the former, and in which mixtilinear spaces may be found, which may be squared as in the preceding cases.

From the point F , if there be drawn any radius FM , intersecting the two circles in R and M , we shall have the mixtilinear space $RAMR$ equal to the rectilinear triangle LAR ; which can be easily demonstrated; for it may be readily seen that the segment AR , of the small circle, is equal to the semi-segment LAM of the greater.

6. Hence, if the diameter MO touch the small circle in F , it follows that the mixtilinear space $ARFMA$ will be equal to the triangle ASF , right-angled at S , or to half the lune $AGCB A$. We might have added here various other properties relating to lunes and their segments, but our limits will not admit of it; we must therefore refer the curious reader to Ozanam's "Mathematical Recreations," where the subject is amply illustrated. See also the remarks of David Gregory, Cawwell, and Wallis, on the quadrature of the lunula, in Phil. Trans. N. 259, or vol. iv. p. 452, New Abridgment; and for "the dimensions of the solids generated by the conversion of the lunula of Hippocrates, and of its parts about several axes, with the surfaces generated by that conversion," see De Moivre's paper in the Philosophical Transactions, N. 205, or vol. iv. p. 565, New Abridgment.

LUNELLE-LA-VILLE, in *Geography*, a town of France, in the department of the Herault, and chief place of a canton, in the district of Montpellier. The place contains 4207, and the canton 9451 inhabitants, on a territory of 145 kilometres, in 11 communes. N. lat. $43^{\circ} 40'$. E. long. $4^{\circ} 13'$.

LUNEN, a town of Germany, in the county of Mark, at the conflux of the Zefick and Lippe; 20 miles S.S.W. of Munster. N. lat. $51^{\circ} 36'$. E. long. $7^{\circ} 37'$.

LUNENBURG, a town of Prussia, in the province of Natangen; 34 miles S.S.E. of Konigsberg.

LUNENBURG, or *Lunenburg*, a city of Westphalia, capital of a principality, situated on the Ilmenau, surrounded with moats and walls, fortified with towers, and containing three churches, about 1300 houses, and 9000 inhabitants. It has also three hospitals, in each of two of which is a church. The prince's palace and the guild-hall are in the market place. The anatomical theatre was built in 1713, and an academy for martial exercises was founded on the site of the convent of St. Michael, which was suppressed. The burghers consist of four orders, the patricians, the brewers, the merchants and tradesmen, and the artisans; and to these four classes some others might be added. Since the year 1639 the magistracy has been composed of one moiety of patricians, and of another of men of letters. The Salze, which is a distinct part of the town, enclosed by wall, has its own separate magistracy. This town consists of fifty-four small houses, sunk in the ground, in each of which are four large leaden pans, containing brine, which is left to exhale for the manufacture of salt; and the salt water is conveyed into them by a common pipe from the several springs. The salt-houses, being 54 in number, and containing 216 pans, which are daily boiled, and every salt-house being estimated at 40,000 rix-dollars, the capital of the whole Salze much exceeds two millions of rix-dollars. Of these salt-works a fifth belongs to the sovereign's due; and the town of Lunenburg pays annually to the treasury near 6000 rix-dollars. Of late the salt-trade has very much declined. The exports of the town are salt, lime furnished by two rocks in its vicinity, and beer. It likewise carries on a trade in wax, honey, wool, flax, linen, and frize. Goods are also brought here from all parts of Germany, and forwarded by the Ilmenau to Hamburg and to Lubek. Lunenburg is 36 miles distant S.E. from Hamburg. N. lat. $53^{\circ} 15'$. E. long. $10^{\circ} 36'$.

LUNENBURG, or **LUNENBURG-Zelle**, a principality of Westphalia, the soil of which is various; consisting of fruitful marsh-land that lies along the Elbe, the Aller, the Jetze, and some other small rivers, other parts, amounting to upwards of 5000 acres, that are sandy, and others that comprehend heath, turf-moors, and swamps. According to the diversity of its soil, it produces wheat, rye, barley, oats, pease, buckwheat, flax, hemp, hops, garden-stuff, oak, beech, fir, pine, birch, and alder. The wheat differs in quantity in different districts, some super-abounding, and the others being deficient; and some breed but few horned cattle and horses, whilst they abound in others. The heaths are covered with numerous flocks of a small kind of sheep, the wool of which is long and coarse. The culture of bees furnishes considerable quantities of honey and wax. The rivers supply plenty of good fish. The river Elbe, which traverses the E. and N. sides of this principality, serves to fertilize the adjacent marsh-lands, and to afford other advantages by its fisheries, navigation, and tolls. This principality contains three large towns, viz. Lunenburg, Velen, and Zelle, with eleven smaller, and thirteen large villages. Its principal manufactures are those of linen, cotton, cloth, ribbons, neckings,

and hats. The king of Great Britain derived from this principality a feat and voice in the college of the princes of the empire, and the circle of Lower Saxony. By the peace of Tilsit, it was annexed to the new kingdom of Westphalia.

LUNENBURG, a county of Virginia, adjoining Newaway, Brunswick, Mecklenburg, and Charlotte counties; about 30 miles long, and 20 broad. It contains 45,576 free inhabitants, and 5876 slaves.—Also, a township in Essex county, in Vermont, seated on Connecticut river, S.W. of Guildhall, and N.E. of Concord, and containing 393 inhabitants.—Also, a township of Worcester county, Massachusetts, on an elevated situation, 25 miles from the Great Monadnock mountain, in New Hampshire. It contains 14,000 acres of land, on which are 1243 inhabitants, and is more distinguished by its salubrity than by its wealth. The inhabitants have little intercourse or trade with their neighbours; but they carry on the mailing business to advantage.—Also, a town of New York, in Green county, now called "Esperanza," situated on the W. side of Hudson's river, opposite to the city of Hudson, and 30 miles S. of Albany. The soil of this thriving village, or town, is uneven, nor is the soil very good.—Also, a county of Nova Scotia, on Mahone bay, on the S. coast of the province, facing the Atlantic ocean. Its chief towns are New Dublin, Lunenburg, Chester, and Blandford. In Mahone bay, La Have, and Liverpool, several ships trade to England with timber and boards.—Also, a township in the above county, situated on Merliquoeth, or Merliquoeth bay, well settled by a number of industrious Germans. The lands are good, and well cultivated; 35 miles S.W. by S. from Halifax.

LUNENSE MARMOR, in the *Natural History of the Ancients*, the name of that species of white marble, now known among us by the name of the Carrara-marble, and distinguished from the statuary kind by its greater hardness and less splendour. It was ever greatly esteemed in building and ornamental works, and is so still. It is of a very close and fine texture, of a very pure white, and next in purity to the Parian marble. It has always been found in great quantities in Italy, and is so to this day. See *Carrara MARBLE*.

LUNES, or **LOWINGS**, in *Falconry*, leathes or longlashes to call in hawks.

LUNETTE, in *Fortification*, an enveloped counterguard, or elevation of earth, made beyond the second ditch, opposite to the places of arms; differing from the ravelins only in their situation.

Lunettes are usually made in ditches full of water, and serve to the same purpose as faussebrays, to dispute the passage of the ditch.

Lunettes are placed on both sides of the ravelin, as B, B. *Plate VIII. Fortification, fig. 8.* to increase the strength of a place: they are constructed by bisecting the faces of the ravelin with the perpendicular I.N., on which are set off 30 toises from the counterfearp of the ditch, for one of its faces; the other face P.N. is found by making the semigorge T.P. of 25 toises; the ditch before the lunette is 12 toises; the parapet three, and the rampart eight. There is sometimes another work made to cover the salient angle of the ravelin, such as A, called *bonnet*, whose faces are parallel to those of the ravelin, and when produced bisect those of the lunettes; the ditch before it being 10 toises. There are likewise some lunettes, whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle, and their semigorges are only 20 toises. Mr. Muller recommends the face P.N. to be perpendicular to that of the bastion, which would then defend it in a direct manner; and if the semigorges of the bonnet A were only seven or eight toises,

toises, it would be less expensive, and its ditch and the covert-way before it would be better defended by the lunettes. *Elem. of Fortif.* p. 36.

LUNETTE, in the *Manege*, is a half horse-shoe, or such a shoe as wants the sponge, *i. e.* that part of the branch which runs towards the quarters of the foot.

LUNETTE is also the name of two small pieces of felt, made round and hollow, to clap upon the eyes of a vicious horse that is apt to bite, and strike with his fore feet, or that will not suffer his rider to mount him.

LUNEVILLE, in *Geography*, a town of France, and principal place of a district, in the department of the Meurthe, situated between the Vesouze and the Meurthe, in a marshy plain, which has been drained. An academy was instituted here by king Stanislaus, and furnished with a good library. The place contains 9797, and the two cantons 22,334 inhabitants, on a territory of 345 kilometres, in 37 communes; 13 miles E.S.E. of Nancy. N. lat. 48° 36'. E. long. 6° 34'.

LUNGKORCKE, a town of Prussia, in the palatinate of Culm; 10 miles N. of Stralsburg.

LUNGOBARDI, in *Ancient Geography*. See LOMBARDS.

LUNGON, in *Geography*, a small island on the W. side of the gulf of Bothnia. N. lat. 62° 40'. E. long. 17° 48'.

LUNGPOUR, a town of the country of Cachar; 15 miles E. of Cospour.

LUNGRO, a town of Naples, in Calabria Citra, chiefly inhabited by Greeks; 10 miles S.S.W. of Cassano.

LUNGRY, a town of Bengal; 36 miles S. of Calcutta. N. lat. 21° 58'. E. long. 87° 35'.

LUNGS, in *Anatomy* and *Physiology*, are organs of the body, situated in the chest, through which the blood passes on its course from the right to the left side of the heart, and in which it is changed from the venous to the arterial state, by means of exposure to the atmospheric air received into these organs in respiration.

The two lungs, (right and left,) are entirely alike in their composition; their size is considerable, and they consist of several different tissues, which render their structure complicated. These tissues are almost all vascular, which gives to the lungs their characteristic spongy and soft nature. They possess, besides the properties arising from their organization, only the insensible organic contractility, or tonic power. Perhaps the muscular fibres of the air-vessels may constitute an exception to this observation. In consequence of their vital properties being limited to this tonic power, they are not capable of any motion in themselves; and they therefore remain motionless, unless some exterior agency puts them in motion; yet, in their functions as respiratory organs, they exhibit a continual movement, an alternation of dilatation and contraction, by which the air is first received into their interior, and then expelled after a certain interval. If this be interrupted for a very short time, the blood is no longer changed, the circulation ceases, and death follows. The lungs then require some auxiliary means for the execution of the functions to which they are destined; these are furnished by the considerable organs of motion surrounding them, which at the same time compose a sufficiently firm defence to protect them against external injury. The ribs with their cartilages, the sternum, and the dorsal vertebrae, form the solid part of the cavity containing the lungs; the diaphragm and intercostal muscles the moveable parts: the cavity itself resulting from their union, is named the thorax. To the sides of this cavity we must refer the pheno-

mena of dilatation and contraction of the lungs, which are entirely passive, and follow the impulse received from this source. Thus the thorax constitutes an essential part of the respiratory apparatus.

But the thorax contains also the central organ of the circulation (the heart), and the large blood-vessels connected with it; thus the apparatus of this function is brought near to, and in a manner confounded at its origin with that of respiration. Yet they are distinct, by the disposition of the common cavity which contains them. For the heart occupies that part of the chest which is formed by the vertebral column behind, by the sternum in front, and by the aponeurotic centre of the diaphragm below; parts which are either immoveable, or capable only of a small degree of motion. The lungs, on the contrary, occupy the most moveable part of the chest; those formed by the ribs and intercostal muscles, and the muscular parts of the diaphragm.

The following account of the respiratory apparatus will include descriptions, 1st, of the chest, in which the lungs are contained; 2dly, of the motions which that part is capable of; 3dly, of the membranes lining the cavities; 4thly, of the lungs themselves; and 5thly, of their functions.

The chest or thorax is a conical cavity, slightly flattened in front, occupying the upper part of the trunk, and consequently having a much larger share of the skeleton below than above it. Yet, if we compare its position to that of the most important organs, we shall find the latter placed almost equally near the viscera contained in the thorax. The parts situated in the head, and those contained in the abdomen differ very little in their distance from the heart; while the latter organ is placed at very unequal distances from the upper and lower extremities. Hence the heart is the centre of the organs contained in the head and abdomen, while it exerts a much less active influence on the lower than on the upper limbs.

The chest is situated in front of the vertebral column; but the curvature of the ribs, which is very prominent behind, causes the cavity to pass a little beyond the spine in that direction, particularly towards the middle. The plane of the front of the chest is posterior to that of the front of the face; commonly it is nearly on a level with that of the abdomen; but the numerous variations of the latter cavity produce corresponding varieties in this respect.

A false idea would be formed of the chest by examining it when covered with soft parts, and articulated to the upper limbs. The numerous muscles surrounding it above, the shoulder, and particularly the clavicle, give to its upper part an extent in the transverse direction, which does not exist in the skeleton, where the chest represents a cone flattened in front and behind, with the basis downwards and the apex upwards. The longitudinal axis of this cone is oblique from above downwards, and behind forwards; but all its sides do not partake equally in this obliquity, which belongs only to the anterior and lateral parts: the posterior, formed by the spine, has no concern in it. Hence a vertical line, drawn from the middle of the space, included between the vertebral column and the ensiform cartilage, perpendicularly through the chest, would not pass out at the centre of the superior aperture, but would go in front of the clavicular extremity of the sternum. The diameters, whether antero-posterior or transverse, of the cone represented by the chest, are all larger in proportion as they are nearer the basis.

In its general capacity the chest holds a middle place between the head and the abdomen. Its depth, from above downwards, is much less in the natural state, than it appears in the skeleton. The diaphragm below forms a considerable arch

arch projecting into the chest, and very considerably lessening its extent in this direction. But this diminution affects the middle, which is occupied by the central tendon, much less than the sides. Again, the clavicles above very manifestly surmount the sternum, and contribute to make the chest appear higher than it really is. The breadth is much less at the upper part, than it appears to be on the first view, because the clavicle and the muscles enlarge the exterior forms without affecting the internal dimensions. The capacity constantly increases in proportion as we proceed downwards. Yet the habit of wearing clothes that are very tight about the waist, particularly stays, contracts that part, so that the chest is sometimes shaped like a barrel, narrow above and below, and broader in the middle. The concavity in the dorsal part of the spine makes the chest more capacious in its middle; yet this enlargement is not equal to the contraction produced by the anterior prominence of the bodies of the vertebrae. In fact, the antero-posterior diameters are all much less extensive along the middle line of the chest than on the sides; so that the sternum is separated from the spine by an interval much smaller than that which exists between the cartilages of the ribs and the hollows at the sides of the spine.

In the female the chest is proportionally broader, but shorter than in the male.

Any cause of distention affecting the abdomen, as pregnancy, ascites, large tumours, &c. strongly elevates the chest, presses the ribs together, and diminishes the perpendicular axis, while the transverse and antero-posterior diameters are rather increased, particularly below. There are malformations of the chest, particularly affecting the sternum and ribs, which diminish the breadth, while they leave the height nearly the same. Individuals predisposed to phthisis are remarkable for this transverse contraction of the cavity, which makes the prominence of the sternum very conspicuous in front. In other instances the chest is affected, in consequence of deformities of the spine: when this is curved, the ribs are brought very close together on one side, and are proportionally separated on the other, so that the two sides of the cavity are rendered very unequal. The chest, in such instances, is generally very prominent.

Description of the particular Bones of the Chest.—It is composed of a common, and of proper parts. The dorsal portion of the spine is the former (see *SPINE*); the sternum in front, and the ribs on each side, are the latter.

The *sternum* is a symmetrical bone, placed in the front and middle of the chest, flattened and elongated, broad above, contracted about the middle, then again becoming a little broader, and terminating at last below by a prominent point. It is divided into a cutaneous and a thoracic surface, a clavicular and an abdominal extremity, and lateral edges.

The cutaneous surface is anterior, covered by the skin, and more immediately by the aponeuroses of the *sterno-mastoidei* and great pectoral muscles: it is marked sometimes by lines dividing it into surfaces of unequal breadths, and corresponding to the original divisions of the bone. It is a little convex at the upper part, and then flattened. The attachment of the muscular fibres, and of the ligaments of the ribs, gives it a roughness. The thoracic surface is posterior, a little concave, smooth, and sometimes exhibits transverse lines similar to those already mentioned. It corresponds above to the *sterno-hyoidei* and *sterno-thyroidei*; then, for a short space, to the cellular tissue of the *mediastinum*, and afterwards to the *triangularis sterni*.

The clavicular extremity is the broadest and thickest part of the bone. Its middle consists of a broad concavity, al-

most entirely occupied by the inter-clavicular ligament: on each side of this is a large superficial excavation, concave from within outwards, and convex from before backwards, articulated to the clavicle, and surrounded by ligamentous insertions. The abdominal extremity is called also the ensiform or xiphoid cartilage or appendix. It is thin, flattened, broader above, and terminating in a narrower way below. Its figure varies greatly in different individuals: the lower end sometimes turns forwards, sometimes backwards; occasionally it is perforated. It generally is cartilaginous, in a greater or less degree, until the later periods of life. It affords insertion to the aponeuroses of the abdominal muscles; the recti cover it in front, and the diaphragm behind.

The margins of the sternum are thick, and exhibit seven articular cavities, to which the cartilages of the true ribs are articulated. These are oblong, and not very smooth. The first, which is superficial, and not clearly marked, is immediately below the concavity that lodges the clavicle. The succeeding ones are separated by slight concavities corresponding to the intercostal spaces, and become nearer and nearer to each other, in proportion as they are placed lower.

The substance of the bone is almost entirely cellular, and its surfaces are covered by a very thin compact stratum of bony texture: hence the sternum is very light in proportion to its size. It consists at first of eight or nine pieces, enclosed in a mass of cartilage: these are soon reduced to seven, and then to five; which number continues for a long time, the individual portions being still separated by cartilaginous strata. The first of these pieces is the largest, and is broader above than below, the two following are nearly square, and very short: the fourth is longer; the last includes the ensiform appendix already mentioned. This division no longer exists in the adult; the pieces are united in the following order. The second is consolidated with the third, and then the latter with the fourth: the other divisions generally continue through life; so that the sternum is ordinarily described as being composed of two bones and a cartilage. The first bone ends at the second rib, which is articulated between it and the second bone. The two pieces are united by a thin layer of cartilage, and their union is often consolidated by bone. The ensiform cartilage is connected in the same way to the end of the second bone; but after a certain age, it is generally more or less ossified.

The *ribs* are bones of irregular figure, placed in succession from above downwards, on each side of the chest, consisting generally, but not constantly, of twelve pairs, flattened and rather thin in front, rounded and thicker behind, and more or less arched. They differ in length, breadth, and direction. The length, which is inconsiderable in the first, is suddenly increased to a very considerable degree in the second; and this augmentation proceeds gradually as far as the eighth. From this they again decrease, so that the twelfth is about as long as the first. The first rib is the broadest; the succeeding ones become narrower, but in an almost insensible degree. Each individual rib is narrowest from its vertebral extremity to the angle: it grows broader in front of this part, and increases to its sternal end. The first rib forms nearly a right angle with the vertebral column; the following are more and more inclined outwards and downwards, so that their vertebral end is higher than their cartilaginous extremities. The first forms a small, but nearly regular semicircle; the succeeding ones form less perfect segments of circles, which increase successively as far as the eighth, and then decrease. All are more curved behind.

hind than in the front: and hence arises the deep excavation on each side of the chest, in the former direction, for lodging the lungs. They are all twisted on themselves, so that the two extremities cannot rest at the same time in an horizontal plane. The point of twisting is at the angle, consequently the first, which has no angle, does not exhibit this circumstance, which is the more sensible in proportion as the angle is more strongly marked. The ribs are distinguished into two classes: the seven superior ones, articulated to the sternum, are called *true*, or thoracic; the five inferior, joined to each other in front by their cartilages, which are not connected to the sternum, are named *false*, or abdominal. Each is divided into a vertebral and a cartilaginous extremity, and a body.

The vertebral extremity is posterior and articulated to the spine. It exhibits a rounded and contracted neck, of about an inch in length, resting on the transverse process of the corresponding vertebra. This neck is slightly expanded at its posterior end, to form the head of the rib, which exhibits a cartilaginous surface for articulation with the vertebral column. The surface is rounded in its outline, single in the first, eleventh, and twelfth ribs, which are each articulated to a single body of a vertebra, and divided by a rising line into two parts in the nine others, which are severally articulated to hollows formed between two vertebrae. Of these two portions the lower is the largest.

The cartilaginous extremity is elongated from above downwards, broad and concave in the ten first ribs, and narrower in the two last. It is most closely joined to the corresponding cartilages, so as to appear perfectly continuous with it.

The body of the rib may be considered under four different points of view; *viz.* the external and internal surfaces, the superior and inferior margins. 1. On the outside it is convex, and presents behind a tubercle, marking the termination of the neck, and divided into two portions: the inner of these is a smooth cartilaginous surface, nearly circular in its figure, articulated to the transverse process of the lower of the two dorsal vertebrae, between the bodies of which the head is articulated; the external is rough, and affords attachment to a strong ligament. This tubercle is confounded with the angle in the first rib, and is deficient in the two last. In front of this eminence is the angle, or part at which the rib, after being continued from the vertebral column obliquely downwards and outwards, turns forwards: instead of being angular, as its name implies, this bend is gentle and rounded. It has a prominent oblique line, not seen in the first and twelfth, but slight in the second and eleventh, and more strongly marked and distant from the tubercle, in proportion as the rib is lower down: it gives attachment to the sacro-lumbalis. Between this angle and the tuberosity there is a surface directed backwards, occupied by the longissimus dorsi, and becoming broader as we trace the ribs from above downwards. The rest of the rib, in front of the angle, forms a nearly smooth surface, directed upwards in the first, where we observe in it two superficial impressions made by the course of the subclavian artery and vein, separated by a surface, in which the scalenus is inserted, and inclined more and more outwards in the succeeding ribs, in proportion as they are lower. In the middle of the second there is a mark from the attachment of the serratus anticus, and on the others analogous impressions from various muscles of the chest and abdomen, as the obliquus externus, pectoralis minor, serratus anticus, serratus posticus, &c.

2. On the inside the surface is uniformly concave and smooth, covered by the pleura, directed downwards in the

first, a little inclined in the same direction in the second, but completely internal in the remainder.

3. Above, the body of the rib forms an obtuse margin, which is internal in the first, inclined upwards in the second, and directly superior in all the others. It affords attachment to the intercostal muscles, except in the first rib.

4. The inferior margin is sharp, particularly near the tubercle, and becomes more obtuse in front. Just within this is found the groove of the rib, which is deep at the back part of the bone, becomes gradually shallower, and is insensibly lost in the front. It lodges the intercostal nerves, but is hardly perceptible in the first and last ribs. This inferior margin affords attachment to the intercostal muscles.

These bones are thin in comparison to their length, and have consequently considerable elasticity, which is not observed in any other part of the skeleton. They are composed mostly of compact bone, with a little cellular structure in their centre: the latter is more abundant at the anterior and posterior extremities. They are developed at an early period in the fœtus, and are more perfect at the time of birth than any other bones, except those belonging to the organ of hearing. They are formed from a single point of ossification, excepting the head, which is not consolidated to the body till the formation of the skeleton is nearly complete.

Sometimes there are thirteen ribs: the thirteenth may be either above or below the ordinary series.

Articulations of the Chest—The chest, formed by bones of an arched figure, most of which rest on the sternum by one end, and by the other on the vertebrae, presents in front and behind articulations corresponding to these relations. The joints, separately considered, do not admit of much motion; but the pectoral cavity, taken altogether, enjoys an extensive power of movement.

The posterior Articulations of the Chest.—The ribs are united to the vertebrae; 1st, by the articular surfaces of their heads to the cavities in the bodies of the vertebrae, each of which cavities is formed in a single vertebra for the first, eleventh, and twelfth, in the two adjoining bones and their connecting fibro cartilage, for the other ribs; 2dly, by the articular surfaces of their tubercles to the transverse processes of the vertebrae, excepting the two last ribs, which have not this kind of articulation. The first has been called the costo-vertebral; the latter the costo-transverse articulation.

The costo-vertebral joints. In each of these the union is effected by means of an anterior and an inter-articular ligament, and two small synovial membranes. The anterior ligament is a broad, thin, flattened, and irregularly quadrilateral fibrous fasciculus, attached in front, above and below the articular surface of the head of the rib, diverging towards the spine, and fixed by its superior fibres to the body of the vertebra that forms the upper part of the corresponding cavity, by its inferior to that which forms the lower, and by the middle to the intermediate fibro-cartilage. The latter are in general less sensible than the two former, each of which forms a very distinct fasciculus. The disposition of this ligament is not exactly the same in the first, eleventh, and twelfth ribs, each of which is articulated to a single vertebra; yet the fibres extend a little on the neighbouring vertebrae. It is covered in front by the great sympathetic nerve, by the pleura, and on the right side by the vena azygos: it has a radiated figure, is short and strong, composed of longer superficial and shorter deep-seated fibres, and has small vascular intervals. It is applied over the joint, for which, in conjunction with the middle

middle costo-transverse ligaments, it may be considered as forming a kind of fibrous capsule.

The inter-articular ligament does not exist in the joints of the first, eleventh, and twelfth ribs. It is a more or less thick fibrous fasciculus, of a flattened figure, fixed on one side to the prominent angle of the head of the rib, and on the other to the corresponding depression of the cavity in which it is received. It separates the two synovial membranes from each other, and is continuous with the fibro-cartilage, as we may perceive by sawing the joint across, so as to divide it into a superior and an inferior half.

The synovial membranes are double in the joints that possess the ligament last described; but in the others there is only a single one, covering the whole extent of the corresponding articular surfaces, and reflected from the one to the other. Where there are two, each capsule belongs to its corresponding upper or lower half of the articulation, and is separated from the other by the inter-articular ligament. These membranes are not clearly marked, do not exhibit the usual polish on their surface, contain a remarkably small quantity of synovia, and occupy often a very small space on account of the great size of the inter-articular ligament. The latter is sometimes so thick, that it may almost be doubted, whether the joint possesses any synovial membrane; in other instances, however, these membranes are very distinct. Although the bones are held together almost as closely as at the anterior articulations between the cartilages and the sternum, the joint is not so frequently lost in the old subject. Yet anchylosis does sometimes occur; and this is a character distinguishing it from joints where the membrane is clearly marked, which may be anchylosed from accident or disease, but hardly ever undergoes this change in the natural progress of ossification.

The *costo-transverse* articulations are formed by a small synovial cavity, a posterior, a middle, and an inferior costo-transverse ligament. The latter does not belong to the tubercle and process which are contiguous: but extends from the process to the upper edge of the rib immediately below. The posterior ligament arises from the end of the process, passes nearly horizontally outwards, and is inserted into the rough eminence of the tubercle of the rib. Its fibres are parallel and close, form a very distinct fasciculus nearly quadrilateral in its figure, correspond behind to the muscles contained in the excavations on the sides of the spinous processes, and in front to the articulation. The middle ligament is a collection of irregular reddish fibres, rather cellular than strictly ligamentous, placed between the front of each transverse process, and the corresponding part of the rib. When we forcibly separate these parts, we distinguish the fibres which are torn by the separation: to see them entire we should saw through the process and rib in their connected state. The inferior ligament is a distinct nervous fasciculus, composed of numerous strong and parallel fibres. It arises from the root of the transverse process, passes obliquely to the upper edge of the rib immediately below, and is inserted near the vertebral extremity. The first and the last ribs do not possess it. It is covered in front by the intercostal vessels and nerves, behind by the *longissimus dorsi*: on the outside it is continuous, by means of a thin aponeurosis, with the intercostal muscle, and it completes on the inside a small cellular space traversed by the posterior branch of the nerves. Between this space and the vertebral column there is commonly a small fibrous fasciculus, arising from the basis of the process, and attached to the articular extremity of the rib below, where it is united to the upper part of the radiated ligament. The two cartilaginous surfaces, of the transverse

process and the tubercle of the rib, are covered by a small synovial membrane, which is looser, contains more synovia, and is always more distinct than that of the preceding joint. Hence it never becomes anchylosed by the mere progress of age.

Anterior Articulations of the Chest—These are not formed by the bony portions of the ribs, but by a series of cartilages terminating them: the seven superior of these are joined to the sternum, while the five inferior, connected to each other, have no other kind of connection. These cartilages must be described before we speak of the articulations. They are not uniform in their length, breadth, and direction. That of the first rib is very short; the succeeding ones increase in length as far as the last of the true ribs. The false ribs again become shorter and shorter, so that it is scarcely perceptible in the last. The first is the broadest, and they become narrower as they are placed lower down. The breadth of the two first is nearly uniform throughout; it diminishes in the others from the costal towards the opposite extremity. This diminution, however, is not regular in the sixth, seventh, and eighth, which are considerably increased in breadth, where they are joined to each other. The first cartilage is a little oblique from above downwards; so that the angle formed between it and the sternum is acute above and obtuse below; the second is nearly horizontal, and follows the same direction as the rib to which it belongs. The following cartilages of the true ribs are more oblique from below upwards, and more manifestly curved where they arise from the ribs in proportion as they are lower. At this curvature the ribs and their cartilages take opposite directions: the first descend from the spine, the others ascend to the sternum. This curvature is diminished a little in the first of the false ribs, where, however, it is still very considerable, and decreases successively to the last, in which the cartilage follows the direction of the bone.

The general figure of the cartilages corresponds to that of the bones to which they are connected. The surface of the body is rather unequal externally, or on the front, slightly convex in most, covered by the *pectoralis major* above, by the *obliquus externus* and *rectus* below. The first gives attachment to the costo-clavicular ligament. Behind or on the inside it is slightly concave, and corresponds in the first five or six to the pleura and triangularis dorsi, to the *transversus abdominis* in the succeeding ones. The upper edge is more or less concave, and the lower convex: they afford attachment to the intercostal muscles, and form a continuation of the intercostal spaces, which, as well as the muscles of the same name, become narrower in proportion as they are lower. Those between the sixth and seventh cartilages, and between the latter and the eighth, are interrupted by small articulations, formed by the contiguous cartilaginous surfaces.

Each cartilage has an external or costal and an internal extremity, which may be also called sternal in the seven first. The former consists of a small convex and unequal surface intimately united to the corresponding concavity in the extremity of the rib. The latter has in the true ribs a small articular surface of a convex figure, adapted to the hollow of the sternum, in which it is received. In the three first false ribs this extremity is elongated, situated immediately under the cartilage above it, and united to it; in the two last it is separated from the cartilage above by a marked interval.

In respect to their structure, the cartilages of the ribs have a great analogy to those of the larynx. Both are very dense and compact, exhibit, at first view, no marks of organization, although they possess really a peculiar structure,

ture, are difficultly reduced into gelatine by boiling, and are remarkable for their tendency to ossification. Even in subjects not much advanced in age, we frequently find a bony point in the centre of these cartilages: this is the commencement of ossification. Those of the first ribs undergo this change most readily: they are often completely bony, while the others still exhibit their natural texture. This ossification is always preceded by a yellowish tint, which succeeds to the white colour that characterizes the cartilages of the child. When they are converted into bone, they resemble the ribs in being compact externally and cellular on the inside. In the rib of an old person the cells of the rib and of its cartilage are continuous.

Articulations of the Cartilages of the true Ribs.—Each of these has a small surface at its internal extremity, received into a corresponding hollow of the edge of the sternum, covered by a thin layer of cartilage. The joint possesses an anterior and a posterior ligament, and a synovial membrane. The seventh rib is moreover united by a peculiar ligament to the ensiform cartilage. The anterior ligament is thin and broad, composed of radiated fibres arising from the extremity of the cartilage, diverging as they traverse the front of the articulation, and expanded on the front of the sternum, where they are mixed with those of the opposite side, with the perioseum, and with the fibres of insertion of the pectoralis major, by which this ligament is covered in front. The superficial fibres are long: the more deeply-seated are shorter, and proceed directly from the cartilage to the neighbouring portion of the sternum. They are intermixed, not only with the opposite fibres, but also with those of the ligament immediately above and below. From the union of all these fibres a thick stratum is formed, covering and strengthening the sternum, and more strongly marked below than above. The posterior ligament differs from the preceding by being thinner and having its fibres less apparent: in other respects they are nearly similar, that is, they proceed in a radiated manner from the cartilages to the sternum. The fibrous stratum on this surface of the bone is as thick as on the other, but it exhibits a more uniform kind of organization. We do not see in it the decussation of numerous distinct fasciculi, but a smooth and almost polished stratum, adhering very closely to the bone, with many of its fibres not derived from the ligaments of the ribs, but pursuing rather a longitudinal direction. The synovial membrane is remarkable for its small extent, and for the want of polish on its surface. If we did not discern a small quantity of synovia in the joint, we might be inclined to doubt the existence of such a membrane. In this respect it very much resembles that of the costo-vertebral articulation. In general, it is rather more loose in the two or three lower articulations, than in the superior ones. In the adult it certainly does not exist in the first: the cartilage is continuous with the bone, which explains the small amount of motion, of which this rib is susceptible. In the articulation of the second rib there is a small inter-articular ligament. A small elongated and very thin fibrous fasciculus goes from the lower edge of the seventh rib obliquely downwards and inwards to the front of the ensiform cartilage, where it forms an angle with the ligament of the opposite side. It is covered by the rectus abdominis.

Articulations of the Cartilages of the false Ribs.—We have stated, that the neighbouring edges of the sixth and seventh, and of the seventh and eighth cartilages, are articulated by means of oblong surfaces. These are covered by synovial membranes much more apparent, more loose, and containing more synovia than those which are found between the supe-

rior cartilages and the sternum. Sometimes between the fifth and sixth, more rarely between the eighth and ninth, a similar articulation, and consequently a similar synovial membrane, are found, which manifestly refer only to the mobility of these cartilages. To maintain the cartilages of the false ribs in their positions, several ligamentous fibres, holding them strongly, particularly in front, pass from the last true to the first false rib; from the latter to the second, and from it to the third. These fibres are particularly evident in front of the synovial membranes which we have mentioned. Analogous fibres attach the extremity of each of the first three false cartilages to the lower portion of the cartilage immediately above it. The only connection of the two last is by means of the muscles. Ligamentous fibres also pass between the cartilages of the sixth and seventh true ribs.

The Chest considered in general.—We shall arrange the description of this cavity under the divisions of its external and internal surface; superior and inferior circumference. The external surface comprises four regions; an anterior or sternal, a posterior or vertebral, and two lateral or costal. The anterior is the narrowest, more or less flattened or projecting in different subjects, and according to the prevalence of certain predispositions. In the middle we have the cutaneous surface of the sternum, on the sides the cartilages of the true ribs, and a series of lines, which indicate in each rib the point of its union with the corresponding cartilage. This series may be conceived as united into one general line, running obliquely from above downwards and from within outwards, forming the lateral boundary of the anterior region, which, from this particular disposition, is much broader below than above. Between these cartilages broad intervals appear in the first true ribs, narrower ones in the last: they are still more narrowed in the first false ribs, but grow broader again in the two last of this class.

The posterior region presents the row of dorsal spinous processes; the corresponding portions of the muscular channels of the vertebræ; the transverse processes of the dorsal vertebræ; their articulations with the tubercles of the ribs; a series of surfaces belonging to the latter, broader in proportion as they are lower, comprehended between the tubercles and the angles, and giving attachment to the longissimus dorsi; and, lastly, a general line running obliquely from above downwards and within outwards, formed by the series of angles of the ribs. The distance between the angles and the tuberosities increasing downwards, determines the obliquity of the line just mentioned, the increasing breadth of the surfaces which it terminates, and the form of this region, which is of considerable breadth below, and becomes narrower as we trace it upwards. This disposition is analogous to that of the anterior region, where the obliquity of the lateral lines produces in the same manner an inequality of breadth.

The lateral regions are convex, narrow above, and broader below, formed by the ribs and the intercostal intervals. The latter are, in general, disposed like the bones which form them, but with some varieties. They are short, and broad above; then diminish successively in breadth, and increase in length down to the junction of the two classes of ribs; after which, without growing broader, they again decrease in length to the last, which is very short: all of them are broader before than behind; hence the distance is much greater between the anterior than the posterior extremities of the first and last ribs. These spaces are all filled by the intercostal muscles.

The internal surface of the chest, which lodges the principal organs of respiration and circulation, also offers four regions to our observation. The anterior entirely resembles that

that of the external surface, and is composed of the same parts. The posterior has in the middle a prominence formed by the bodies of the dorsal vertebrae, concave from above downwards, and dividing the chest into two internal halves. On each side of this is a considerable elongated concavity, narrow above, broad below, deeper in the middle than in any other part, and containing the posterior convexity of the lungs. The lateral regions are concave; formed by the internal surfaces of the ribs and the intercostal spaces. The pleura lines them, as well as the posterior hollows and the pectoral portion, excepting as much of the latter as corresponds to the mediastinum.

The superior circumference is small, in comparison with the inferior, and represents an oval placed transversely. It is formed behind by the vertebral column, in front by the sternum, and on the sides by the first ribs: the clavicles project a little at their inner ends, so as to contract this opening in a slight degree. The trachea, the œsophagus, the large blood-vessels, which either go from the heart to the upper parts of the body, or return from the latter to the heart, and several important nerves pass through this opening.

The inferior circumference is very large, at least four times greater than the former, and differs from it in being susceptible of enlargement and contraction. The superior, formed by two ribs nearly immovable, preserves always the same capacity, and is, moreover, protected by a considerable thickness of parts from the impressions of extraneous bodies, that might tend to contract it. To the mobility of the inferior circumference are chiefly owing the variations in the dimensions of the chest, produced by inspiration and expiration, by causes which act on it from within outwards, and dilate it, as dropsy, pregnancy, and the various abdominal tumours, or by those which affect it in the contrary way, and tend to contract it, as the stays of women. It should be observed, at the same time, that the viscera placed at this circumference can accommodate themselves to these varied dimensions: while those which pass through the superior aperture, particularly the trachea, would be affected very dangerously by any contraction of its sides. In this inferior circumference there is a large notch in front, of a triangular figure, with the basis downwards, the sides of which are formed by the edges of the cartilages of the false ribs: in the apex of the triangle the ensiform cartilage projects. On each side of this notch there is a convex edge, formed by the cartilages of the false ribs. Behind these convexities there is a small notch on each side, formed by the inclination of the last rib, with respect to the vertebral column. Several of the abdominal muscles are attached to all parts of this circumference.

Development of the Chest.—The heart and the thymus, which are situated on the median line of the chest, in the fetus, and are of very considerable size, require a proportional extent in the antero-posterior diameters, which then predominate, while the transverse are comparatively small, on account of the imperfect condition of the lungs. The sternum, separated by a wide interval from the spine, makes a considerable prominence in front, so that a large space is left for the heart and thymus. The posterior fossæ, at the sides of the vertebral column, are small, as the ribs are not much curved at this part: hence the prominences behind, formed at the sides of the spine by the curves of the ribs, are not sensible at this time. The chest is particularly narrow in this direction at the angles of the ribs. The want of this posterior curvature is the principal cause of the augmentation of the antero-posterior diameters. In fact, the ribs are nearly as long, proportionally, at this time as after-

wards; but they swell less behind and at the sides, are thrown more forwards, and, consequently, carry the sternum in that direction. These curves are formed in the progress of age; the posterior fossæ of the chest are, consequently, developed, and the sternum comes nearer to the spine. The transverse diameters are now increased; but the general capacity of the chest is not much augmented in proportion to other parts, as it loses in one direction what it gains in the other, and its differences in the fetus, and in the subsequent times, are referrible to the different relations of its diameters. These changes affect the superior and inferior circumferences. The former is more capacious from before backwards, but less from side to side: the latter is very wide between the ensiform cartilage and the spine; it is one-third wider here than in the adult, in proportion. The transverse diameters are less contracted here than in the rest of the chest; so that the inferior circumference altogether is remarkable for its great capacity in the fetus, a disposition which is accommodated to the very marked volume of the gastric viscera, and particularly of the liver, which it includes.

The different bones of the chest are not developed in an uniform proportion. The ribs are almost entirely ossified at the time of birth: they are more approximated, particularly below, probably from the great size of the liver. The perfection in the ossification of the ribs may be explained from the nature of the function in which they are employed. Respiration commences at the moment of birth, and requires in its organs as great a degree of perfection as is necessary at any subsequent age: the newly-born child respires at once as it will respire always. The organs of locomotion, on the contrary, go through a kind of education, advance very slowly to perfection, and are, consequently, slowly developed.

The sternum, which is less directly concerned in respiration, but concurs more immediately in giving solidity to the chest, is not so much advanced as the ribs: on the contrary, it is almost entirely cartilaginous.

The contents of the thorax undergo a great change at the time of birth: the lungs, hitherto contracted, are distended by the admission of air to a much greater volume than they possessed before; and that part of the chest which contains them must be proportionally increased.

Towards the period of puberty, although no remarkable change occurs in the ordinary series of phenomena connected with the growth and progress of the bones, yet the form of the chest seems to acquire its fixed character. It either assumes that lateral expansion, and happy conformation which indicate a vigorous constitution, or the sternum projects in front, and gives the alarming presage of a disposition to phthisis. At this time the cartilages become more dense, and the ligaments stiffer. The motions of the ribs are more confined. Hitherto they have been the chief agents in respiration: but in future the diaphragm is more excited. The different pieces of the sternum are joined; the ribs receive more earthy matter, and become more brittle. At a later period the cartilages begin to be converted into bone at their centres, and ossification goes on until they are made completely bony. The twisting of the cartilages, which we shall mention presently, is now impossible, and the upper part of the chest no longer admits of motion in its individual parts. Hence in the old subject respiration is effected chiefly by the diaphragm.

Mechanism of the Chest.—This part of the trunk has two principal uses to fulfil: it protects the included organs by its solidity or power of resistance; and it concurs by its mobility in the various functions of these organs, particularly of

the lungs. We have to consider it under this double point of view.

The resistance of the chest to the action of external force is different on its anterior, posterior, and lateral aspects.

1. The thick muscles placed behind annihilate the effects of falls and blows on that part. Two prominences formed by these muscles, and separated by a groove corresponding to the spinous processes, occupy the place of the two longitudinal channels observed in the skeleton: these support the effects of blows. The provisions for protection in this situation, refer to the spinal marrow as much as to the pectoral viscera. 2. In front, where the muscles are fewer, the mode of resistance varies in inspiration and expiration. When the chest is strongly dilated, the sternum supports any effort directed against it in the manner of an arch, and more efficaciously in proportion as the inspiration is stronger. In this way, individuals lying on their backs support enormous weights on the front of the chest: e. g. a blacksmith's anvil, on which a horse-shoe has at the same time been hammered. Here, however, the mechanism is not the same as that by which the cranium supports a weight bearing on it perpendicularly: in that case the bony arch alone is concerned, the muscles have nothing to do with the phenomenon. In the chest, on the contrary, the external muscles, particularly the serratus anticus, draw the ribs strongly outwards, and resist their depression: they are the active supports of the bony arch represented by the chest. If the force be superior to the resistance, fracture ensues: this may either be direct, and affect the sternum, which is rare; or it may take place by contrecoup at the part which has experienced the greatest effort, as in the middle of the ribs. These observations manifestly apply to the true ribs only. Fractures by contrecoup may also take place from sudden blows, where the muscles have no time to contract and support the ribs, and the latter are consequently left to the full operation of the force. In expiration the chest eludes the force by yielding: the ribs are pressed inwards, and the viscera are in some degree compressed. This yielding is much more manifest in the lower ribs. 3. The effects of blows, or violence of other kinds, affecting the sides of the chest, are obviated in nearly the same manner, whether in inspiration or expiration. The arch represented by the rib has its points of support in the sternum and the vertebral column: the bone may be directly fractured at the point where the violence is offered, which is the most common case, or by contrecoup, which is more rare. The strength of the ligaments at the anterior and posterior articulations is so considerable, and the support afforded by the transverse processes so firm, that luxations cannot take place while the joints are in a healthy state. The last ribs, which terminate loosely in the abdominal parietes, cannot be said to offer any resistance to the force which is applied to them: they yield towards the abdomen. The first and second ribs are so covered by external parts, that they can hardly be affected by blows or other kinds of force.

The motions of the chest are directed to two principal objects; its dilatation and contraction, which correspond to inspiration and expiration. It may be dilated in three different directions; perpendicularly, transversely, and from before backwards. 1. The diaphragm alone is the agent of perpendicular dilatation, and produces alone in the adult those slight inspirations, in which but little air enters the chest. Its fleshy sides, which correspond to the lungs, descend much more than the tendinous centre, which supports the heart. (See DIAPHRAGM.) 2. In the next or greater degree of inspiration the chest is first dilated perpendicularly, and then transversely by the intercostal muscles. (See INTERCOS-

TALES.) Besides the causes mentioned in that article for the little power of motion in the first rib, we may notice the inconsiderable length and great breadth of its cartilage, and its consolidation with the sternum, instead of being joined by a moveable articulation. The remarkable shortness and breadth of the rib itself also concur in producing the same effect. In consequence of the oblique position of the ribs, they cannot be elevated without having their middle carried outwards, which produces a transverse enlargement of the chest; moreover, this elevation twists the cartilages, which throws the ribs still more outwards. 3. In the preceding motion the ribs are carried a little forwards, and as this effect takes place in a greater degree below, where the ribs are longest, the sternum is carried forwards at its lower extremity, the upper remaining nearly motionless; and the chest is consequently enlarged from before backwards. This motion, however, is very small in amount, as we may ascertain by observing the respiration of a lean individual; it is insignificant in comparison to the motion by which the ribs are carried outwards. As the sternum corresponds to the heart, while the ribs surround the lungs, enlargement is less needed in the former than the latter direction.

The contraction of the chest, corresponding to expiration, is effected by a mechanism exactly opposite to that which we have just explained. It takes place from below upwards by the elevation of the diaphragm. In the transverse direction it is effected by the depression of the ribs, which are carried inwards by the twisted cartilages recovering their original state. The elevation of the bone in inspiration produces a twisting of the cartilage; and in expiration the recovery of the latter depresses the former; so that the bone and the cartilage reciprocally determine motion in each other. The effect of this twisting of the cartilages must not, however, be over-rated: in order to make it considerable, they ought to be consolidated to the sternum, whereas their articulation to that bone allows a certain degree of motion. The greater this motion, the less will be the twisting; and it would not exist at all if the articulation were loose enough to allow full scope to the elevation of the rib. It cannot have any effect in the false ribs. In proportion as the ribs descend and are carried inwards, the sternum is also restored, its inferior portion passing backwards.

All these movements, whether of dilatation or contraction, are much more sensible at the lower part of the chest, in consequence of the more extensive motion enjoyed in this part; a circumstance that coincides with the greater breadth of the inferior portion of the lungs.

We have to point out, in the next place, the powers by which these motions of the chest are effected. We may distinguish two kinds of changes taking place in the chest; an enlargement and subsequent contraction in the perpendicular direction, and another acting circularly. The diaphragm is the sole agent of the perpendicular enlargement; and as it extends the chest downwards, where the cavity is most ample, it produces a very considerable dilatation. (See DIAPHRAGM.) This muscle can descend three inches, or more, and has four or five times as much effect in the enlargement of the chest, as all the other powers put together. Hence injuries or diseases of it produce the greatest disturbance in the function of respiration. The perpendicular contraction is effected by the abdominal muscles; that is, by the obliqui externi and interni abdominis, the transversi and recti. These, which form the sides and front of the abdominal parietes, yield to the viscera thrust downwards by the descent of the diaphragm: hence an elevation of the belly is perceptible on inspiration. They then contract, push backwards and upwards the parts which had before descended, restore

restore the diaphragm to its former state, and consequently diminish the capacity of the chest.

The enlargement of the thorax in the circular direction is ordinarily effected by the intercostal muscles, (see INTERCOSTALES); and the subsequent contraction is owing partly to the restoration of the ribs by the elastic power of their cartilages, and partly to the action of the triangularis sterni. But other powers assist occasionally, when the circulation and consequently the breathing are hurried; or when disease of the chest causes this function to be performed laboriously. Under such circumstances, every muscle is brought into action that can assist in elevating the sternum or ribs, or in fixing the upper pairs of these bones. Hence the scaleni, sterno-cleido-mastoidei, subclavii, cervicales descendentes, levatores costarum, serrati magni, serrati postici superiores, latissimi dorsi, pectorales majores & minores, and trapezii, are all employed. The shoulders are elevated, the neck is stretched, and the head itself thrown backwards in the most violent efforts of difficult expiration. There are also auxiliary powers occasionally employed in expiration, but these are not so numerous as those concerned in inspiration. The ribs may be depressed, not only by the triangularis sterni, but also by the obliqui, recti and transversi abdominis, the quadrati lumborum, longissimi dorsi, sacro-lumbalis, and serrati postici inferiores.

In the healthy subject the enlargement and contraction of the chest constantly succeed each other, and are performed in a regular alternate manner. The diaphragm and abdominal muscles seem to be chiefly employed; but the intercostal muscles also assist. In the female the latter powers are more concerned in respiration than in the male.

Although both modes of respiration are observed to concur in this function in the natural state, it may be and often is carried on by one exclusively. When a rib is broken, or the pleura inflamed, motion of the chest is exceedingly painful, and the diaphragm and abdominal muscles carry on the functions alone. On the contrary, in inflammation of the peritoneum, in the last periods of pregnancy, in large dropical accumulations, the abdominal muscles and diaphragm cannot act, and the intercostals only are then concerned.

In ordinary respiration, enlargement and contraction of the chest, or inspiration and expiration, are performed in regular alternate succession; but this order is often interrupted, and various modifications of the process take place, distinguished by particular names.

In *straining*, the diaphragm and abdominal muscles act together; a deep inspiration is first made, and the diaphragm descends considerably; the abdominal muscles then contract, but do not expel air from the chest, as they are resisted by the former power. The act of straining takes place in all powerful exertions of the body: by it the trunk is fixed, and affords a firm point from which the limbs may be most advantageously moved. The erectors of the spine at the same time extend that part, and firmly maintain it in that position. Thus all the power of the muscles moving the limbs is employed in jumping, dragging, pushing, moving a weight, &c.; and none is left in moving the thorax or pelvis towards the limbs, which would be the case if those parts of the trunk were not previously fixed. So long as the effort lasts, it is obvious that respiration must be interrupted; hence it is called, in common language, holding the breath: and when it is too long continued, all the inconveniences arising from such interruption take place.

The powerful action of the diaphragm and abdominal muscles subjects the contents of the abdomen to pressure: it impels them and whatever they may contain towards the cavity

of the pelvis, and must also compress the blood-vessels and absorbents. Hence this effort is employed in expelling the contents of the stomach in vomiting, in evacuating the rectum and urinary bladder, and in parturition; it is so essential in all these cases, that the different objects just mentioned could not be accomplished without it. Of the amount of the force exerted we may form some estimate, when we see the effects occasionally produced by such efforts;—the contents of the abdomen are protruded and form tumours, the viscera are torn, and the tendons of the abdominal muscles lacerated.

Whether the passage of bile through its ducts, or of calculus through the same tubes or the ureters be facilitated by straining, is a doubtful point.

In *panting* there are short and frequent inspirations, succeeded by short and quick expirations. It is accompanied with great anxiety, and is attended with, or caused by, a more rapid return of blood to the lungs; hence it heats and fatigues. It is produced by violent motion of the body, in wounds of the chest, in diseases of the respiratory organs, and of en in the struggle preceding death.

A long and deep inspiration, followed by an expiration of the same kind, constitutes a *sigh*. It seems to be an effort at promoting the passage of the blood through the lungs; and has been said to be employed when the action of the heart is languid, when it is oppressed by the quantity of the blood, or when obstacles exist to its passage through the lungs. Sighing takes place under mental affliction or considerable bodily fatigue: we generally recover from a state of syncope by a sigh, and asthmatic persons frequently sigh.

In *yawning* there is a still larger inspiration than in sighing, performed in a very slow and protracted manner, and accompanied by a similar corresponding expiration. In both a peculiar sound is usually produced. The mouth is opened widely, indeed to the utmost extent that the articulation of the lower jaw will allow. Yawning is often ended by a sigh. That it is produced by bodily fatigue, observed most frequently on the approach of sleep and on waking, and takes place also when hunger is troublesome; also that newly born children yawn in their first attempts at respiration, are well known facts, but we cannot explain how this happens. Soemmerring says, "that the circulation of the blood through the lungs goes on more slowly before yawning; and that we endeavour to obviate by a strong inspiration, which may promote the circulation through the lungs, the sense of weight, inconvenience, and sleepiness that would arise from this cause." De Corporis humani Fabrica, t. vi. p. 82.

Coughing is an effort of the respiratory organs, generally made for the purpose of removing from the trachea or its branches some irritating matter, as mucus, pus, or any foreign body, through the means of powerful expirations, preceded by similar inspirations. Yet the presence of a stimulus in the situation just mentioned is not necessary, although it is the most frequent cause: irritation of the diaphragm, as from diseased liver, or an action of the will, can produce coughing. A large quantity of air furnished by a considerable inspiration, is violently and suddenly expelled, with a considerable noise, by a very strong and almost convulsive expiration, and in its passage clears away mucus, or any thing else which may happen to be in the air passages. The air may be driven out at once or at several expirations: in the latter case the expirations are continued often as long as any air can be expelled, and the emptied chest is again supplied by an inspiration accompanied with a peculiar noise, as in the whooping cough. Violent and protracted coughing from the interruption of the respiratory phenomena, is accompanied with turgescence and livid colour of the

the parts about the head, and with a sense of suffocation: when continued for a long time it causes head-ache, soreness of the chest, &c.

Sneezing is an action similar in its nature, but more violent in degree than coughing; and it has a different cause, *viz.* irritation of the membrane lining the nose. A short but generally full inspiration is followed by a most vehement expiration, shaking almost the whole body. The expelled air, which in coughing passes through the mouth, is directed in sneezing, through the nose, for the purpose of removing the irritating cause. Any extraneous bodies brought into contact with the pituitary membrane, as instruments or irritating powders, such as snuff, &c. or its own mucous secretion, and in some individuals sudden exposure to strong and dazzling light, will produce sneezing. Although it is an involuntary effort, it may be in some degree increased or diminished by the will. It is a singular fact, that pressure about the bridge of the nose, applied when the inclination is felt, will generally prevent it.

How far the following observation of Soemmering tends to elucidate the manner in which stimuli applied to the pituitary membrane act on the respiratory muscles, in exciting this convulsive motion of them, is left to the judgment of the reader. "Sneezing arises from some re-action of the brain, when irritated, through the medium of the nasal nerves, *i. e.* the olfactory and fifth pairs, upon the phrenic nerve; and that it must be produced in this way is proved by the fact, that the phrenic and these nerves have no connection out of the head." *De Corporis humani Fabrica*, t. vi. p. 84.

In *laughing*, a full inspiration is followed by frequent, imperfect, and as it were broken expirations, by which the chest is not completely emptied. As respiration is hurried beyond its natural rate in this act, the circulation is rather quickened; and from the convulsive kind of action in which it consists, a general agitation must be imparted to the abdominal contents. In many individuals, a very obvious shaking of the chest and abdomen accompanies laughter, particularly when violent, so as to have become matter of very common observation: hence the soreness experienced from its long continuance. The features are at the same time affected in a peculiar manner. In some individuals the latter circumstance is chiefly observed. The slightest cases of laughter, which are rather called smiling, consist merely of this change of features; but when it goes further, the diaphragm and abdominal muscles are brought into action. A considerable production of sound takes place at the same time, representing in men chiefly the vowels *a* and *o*; in women *e* and *i*. The mouth and its neighbouring parts are principally affected in the face; the corners are drawn upwards and outwards, so as in many cases to expose the teeth; the cheek is swelled, and the general elevation of the integuments raises the lower eye-lid, so as to contract the aperture between the two lids. As the interruption in the regular performance of respiration produces turbulence about the head in violent and long continued laughter, the lacrymal secretion is augmented, and a copious flow of tears often ensues.

The causes of laughter are partly moral and partly physical; with the former we have nothing to do in this article, except to observe that laughing and weeping seem quite peculiar to the human subject. Gentle friction and pressure of various parts of the body, as the soles of the feet, the axillæ, hypochondria, &c. commonly called tickling, are the chief of the latter kind.

Involuntary laughter is a symptom of some diseases, as hysteria; and the ancients were of opinion that injuries of

the diaphragm produced it: in this case they called it *risus sardoniacus*. Modern observations do not confirm this fact.

Weeping begins with a deep inspiration, which is followed by short, interrupted expirations, at longer intervals from each other than in laughing: these often shake the thorax and abdomen, and even the head. They are finished at last by a strong expiration, followed by another inspiration or a sigh. This, like laughing, is generally produced by certain mental affections; but in some instances it owes its origin to physical causes, as bodily pain; and diseases, as hysteria, hypochondriasis, &c. Children generally cry immediately on their birth. The features are considerably affected in weeping; the eye-lids are contracted, and the forehead wrinkled: the mouth has its corners drawn downwards.

Hiccough is sometimes associated with weeping. It consists of a full, violent, sonorous, and short, or sometimes even convulsive involuntary inspiration through a contracted glottis. Some consider that the epiglottis is concerned in producing the peculiar sound of hiccough, and that this organ is struck by the air as it forcibly enters the larynx. The diaphragm appears to be the part principally concerned in this convulsive inspiration. Sometimes an expulsion of air from the stomach through the œsophagus is joined with hiccough. Two, three, or more natural inspirations and expirations take place in the interval between two hiccoughs. It may be occasionally prevented by depressing the diaphragm, and thus holding the breath; or by swallowing something slowly.

There are many causes exciting it. The nearness of the stomach to the diaphragm occasions the latter to be often affected by particular states of the former organ. Eating or drinking too much, or unwholesome articles, is a frequent source of the complaint. Wounds or diseases of the stomach, or of the diaphragm, may produce it; as also various general diseases of the frame, in which it often appears as the precursor of death.

Inspiration is immediately concerned in the act of *sucking*. The lips are closely applied round an object, *e. g.* those of the child to the mother's nipple. The air contained in the mouth is then more or less completely exhausted by inspiration, and the pressure of the surrounding air forces into this more or less complete vacuum the contents of the lactiferous tubes. When a liquid is sucked through a tube into the mouth, the vacuum is formed in that tube, which is embraced by the lips, and the air, pressing on the surface of the liquor, forces it up the tube into the mouth. If the lips are directly immersed in the fluid, a vacuum is formed, and the fluid rises into it exactly in the same way. The act of *drinking* is effected on the same principles.

Description of the Pleura and Mediastinum.—The pleura is a thin transparent serous membrane, lining the cavity of the thorax, and reflected over the contained lungs. Each of the latter organs is enclosed in a particular bag of its own, which bears the same relation to the lung, as the pericardium does to the heart; surrounding it like a loose bag or sheath, and immediately investing its surface: hence we naturally distinguish two parts of this membrane, *viz.* the lining of the chest (pleura costalis), and the external covering of the lung (pleura pulmonalis.)

As there are two lungs, there must also be two pleuræ, a right and a left. We may form a notion of them by conceiving two membranous bags, forming entire and imperforated cavities, placed laterally with respect to each other, and forming, by their apposition, a partition dividing the chest into a right and a left side, and containing in its substance several of the organs belonging to this cavity. That the two membranous bags are perfectly distinct, so that

that nothing can pass from one to the other, is rendered obvious; 1st, by anatomical examinations, in which they may be separated without any injury; 2dly, by experiments on dead bodies, in which fluids may be thrown into one pleura without passing into the other; and 3dly, by observations on diseased subjects, in which water, pus, &c. are often contained for long periods in one pleura only.

In order to understand the relations of the pleura to the lungs and to the other thoracic organs, let us describe it as if it began behind the sternum. From this part it extends outwards, covering the ribs, their cartilages, and the internal intercostal muscles, consequently lining the sides of the chest. At the heads of the ribs it covers the ganglia of the great sympathetic nerve, and their branches. When it has reached the back of the cavity, and the vertebral column, instead of passing in front of that column, it is continued from behind forwards, on the side of the aorta and the œsophagus, in front of which it is applied against the membrane of the opposite side, to form the posterior part of the mediastinum. It would be continued in this way from the spine to the sternum through the whole length of the chest, if it did not meet with the fasciculus of vessels entering the root of the lung; it is reflected over these, and over the surface of the lung, to the substance of which it is closely connected, forming its exterior covering. At the front of the root of the lung it covers the anterior surface of these vessels: then is continued from behind forwards on the side of the pericardium. It is then applied to the bag of the opposite side, to form the front of the mediastinum, and, lastly, terminates on the back of the sternum, where we supposed it to begin. Below it extends over the whole superior surface of the diaphragm.

Thus it appears that the figure of the pleura is completely determined by that of the cavity which the membranes line. Each of these bags is conical: it rises into an obtuse point within the space included by the first rib; on the anterior, outer, and posterior aspects it is convex, where it lines the ribs and intercostal muscles; below it is concave and expanded over the diaphragm; and on the inside, where it contributes to the mediastinum, nearly plane, but slightly concave in the situation of the heart. Some anatomists distinguish in the pleura three portions, according to the parts of the chest which they cover: *viz.* the costal, the diaphragmatic, and the mediastinal.

The pleura adhere with different degrees of firmness to the parts which they line. The medium of this connection is a cellular tissue, continuous below with that of the abdominal parietes, above with that of the neck and upper extremities, and in all directions with that which fills the interstices of the muscles forming the sides of the cavity. In the neighbourhood of the vertebrae, and in some parts of the mediastinum, this tissue is copious, and often contains fat: the adhesion is closer to the ribs and intercostal muscles, and most firm to the diaphragm.

The relative situation of the two bags varies at different parts of the chest, as different organs are interposed between them. Towards the upper and anterior part, immediately under their obtuse points, behind the arteries coming from the arch of the aorta, and above the pericardium, they are contiguous and separated only by cellular texture. In the middle and lower part of the chest, they are widely separated by the intervention of the heart, pericardium, large blood-vessels, &c. Hence the axis of the cavity must pass from above obliquely downwards and outwards.

The right and left do not precisely correspond to each other. The former, on account of the oblique position of the heart, lines nearly the whole posterior surface of the

sternum: hence it is broader than the left; but it is at the same time shorter, because the diaphragm is more strongly arched on this side. The left is applied, for the space of some inches, to the aorta.

The capacity of the two pleurae taken together is about one hundred cubic inches in the dead body. It is generally larger in the male than in the female sex; and is very disproportionately small before birth. The right encloses the left in the same proportion as the right is larger than the left lung.

The *mediastinum* is the partition which separates the two bags of the pleurae, and divides the chest into a right and a left side. It is formed by the apposition of the two membranous sacs, and extends from the vertebral column to the sternum and cartilages of the last ribs. We describe in it two lateral surfaces, a posterior and an anterior edge, a basis and an apex. The lateral surfaces are smooth, and contiguous to the internal surfaces of the lung, except where the pulmonary vessels enter those organs: they form the inner portions of the two bags of the pleura. The posterior edge is attached to the spine, of which it exactly follows the direction. The anterior is fixed in an oblique line to the sternum above, and to its edge and the cartilages of the last ribs below. Hence, if we thrust a pointed instrument through the middle of that bone, it will penetrate the right pleura, and not touch the mediastinum. The oblique position of the heart seems to carry with it, as a consequence, this obliquity of the mediastinum. Yet this disposition does not hold universally: in some subjects the mediastinum descends along the middle of the sternum: in others, which indeed are very rare, it is inclined from left to right, so that the right side of the chest is narrower than the left. Sometimes the right layer of the mediastinum is fixed to the middle of the sternum, while the left is attached at the articulations of the cartilages. The basis of the mediastinum corresponds to the superior surface of the diaphragm, and presents a wide separation of the pleurae, lodging the heart and pericardium. The apex corresponds to the upper end of the chest; it encloses the trachea, the œsophagus, and the vessels and nerves which are entering into or going out of the chest.

The mediastinum is formed by the two pleurae, which, instead of coming into contact with each other, leave a considerable interval between them filled by various organs. Above and in front, they lodge the thymus: below and in front, the heart with its pericardium, and the large vessels connected to its basis: behind, the œsophagus and aorta. The two laminae of the mediastinum touch each other only in front of the pericardium, between the lower end of the thymus and the diaphragm, and behind that membrane, in front of the œsophagus, from the first dorsal vertebra to the cardiac orifice of the diaphragm. The latter circumstance has occasioned a division of the mediastinum into an anterior and a posterior part; the first includes all that is placed in front of the œsophagus, the latter all behind it. These divisions are often called anterior and posterior, or sternal and dorsal mediastina. The former is the broadest and shortest of the two; it ends about the fifth or sixth rib: while the latter extends to the eleventh.

In the anterior mediastinum, or triangular space placed behind the sternum and cartilages of the last ribs, besides some fat and cellular substance, and some absorbing glands, we have the thymus, the trunks of the internal mammary arteries, and the heart. In the posterior mediastinum, or interval of the pleura immediately in front of the vertebrae, are found, in addition to some adipous and cellular texture, and several absorbing glands, the end of the trachea

with the commencement of the bronchi, the greatest part of the œsophagus, with the nerves of the eighth pair, the pulmonary artery and veins, the descending aorta, the thoracic duct, and the vena azygos.

When the sternum is raised, in order to expose the contents of the thorax, the space separating the two pleuræ behind that bone, and forming the anterior mediastinum, is increased, because the membranes are partly detached from the sternum and ribs, to which they before adhered. The cellular substance occupying the interval becomes filled with air, and is consequently rendered more sensible.

The laminae composing the mediastinum are rather thinner than the pleuræ in other situations. They are united to each other, and to the parts included between them, by a cellular tissue continuous with that of the general external surface of these bags. This tissue, as well as that connecting the different parts together, is tolerably copious, and contains more or less fat. It is susceptible of inflammation and suppuration, as in other parts of the body; but less frequently. Hence abscesses sometimes occur here. The laminae of the mediastinum are, however, more closely attached to the surface of the pericardium; it is difficult to separate the two membranes completely. The right lamina is more tense than the left; a considerable protuberance is observed in the latter, and formed by the situation of the heart: hence the former only, if either, can have any effect in supporting the diaphragm.

The mediastinum receives its peculiar blood-vessels. In front its arteries come from the internal mammary, and the comes nervi phrenici; behind, from the inferior thyroid, the superior intercostal, the pericardiac, œsophageal, and bronchial arteries. The veins correspond to, and accompany these.

The mediastinum divides the chest into two lateral halves; separates the membranous bags containing the lungs, and renders their action independent of each other. It confines also to one side various morbid affections, as effusions of blood, pus, &c. Some physiologists conceive that it is further useful, by supporting the weight of the opposite lung, when we lie on the one side, and protecting therefore the lung of the same side on which we lie.

The pleura is nearly transparent, so that we can easily distinguish through it the colours of the subjacent parts. The fibres of the diaphragm and intercostal muscles, the intercostal vessels and the ribs are immediately discerned through this membrane. We can still more clearly perceive all the shades of colour in the lung through the pleura pulmonalis; this indeed is thinner than the pleura costalis, and adheres very closely to the organ. Boiling destroys this transparency, and gives the membrane a dirtyish white appearance. It is very strong in proportion to its thickness. Concerning its intimate organization we have nothing farther to say than what the reader will find in the general account of the serous membranes.

The arteries and veins of the pleuræ, besides what have been already mentioned as belonging to the mediastinum, are derived chiefly from the intercostal vessels. The absorbents are exceedingly numerous, and pass through glands situated about the heads of the ribs to the thoracic duct.

The internal surface of the pleura is in all parts smooth, pale, and covered by a serous moisture produced from the exhaling vessels of the membrane. This observation applies as well to the pleura pulmonalis as to the p. costalis: the internal surface of the former constitutes the outer surface of the lung: the two portions of the membrane are contiguous at all points. In a living animal, or in one recently slaughtered, and opened whilst yet warm, this serous exhalation ef-

apes in the form of a light whitish smoke: the surface of the membrane has a soft slippery feel, but no actual fluid is discerned in the chest. When the body has cooled, this vapour is condensed into a few drops of liquor, which is soon increased by the transudation through the blood-vessels, and then it constitutes what authors have described under the name of liquor pleuræ. It has been questioned whether this, or the fluid of the pericardium, which is also in very small quantity, composed the watery part of what issued from the side of our Saviour when pierced by the soldier. We are of opinion, that the period, at which this occurred after death, was too recent for us to suppose that any fluid, or if any, not more than an exceedingly minute portion of fluid, could be contained in the pleura or pericardium. Consequently the fact does not admit of a natural explanation, but must be referred to the miraculous powers so signally exerted in other respects on this occasion.

This serous exhalation is constantly absorbed and renewed. It keeps the lung in an insulated state, and separates it from the parietes of the thorax. How far this is essential to the functions of the organ, will be examined presently.

The exhalation of the pleura is variously changed in disease. It consists of actual fluid, either deposited in unusual abundance, or not absorbed with the usual activity, in hydrothorax. In pleuritis it is the coagulating part of the blood, which afterwards forms the adhesions of the two pleuræ, so commonly seen in the dead body, that hardly any subject is entirely free from them.

As the pleura pulmonalis and costalis are always contiguous, it follows that the lung always fills the cavity of this membranous bag. If we dissect away carefully the muscular parts, that fill the interval of two ribs, so as to expose, without penetrating the pleura, the transparency of the latter membrane allows us to see the lung through it, and to see that there is no interval between them, but that they are in accurate contact in all parts of the chest. The result of this examination is the same, both in the living and the dead subject. From this representation it follows that the motions of the chest must be accompanied by corresponding changes of the lungs; that air will enter into or pass out of those organs through the trachea, which is constantly open, according as the chest is enlarged or diminished; and, in fact, that the dilatation and contraction of the thorax are constantly attended with a similar dilatation and contraction of the lungs. These motions of the chest refer entirely to the functions of the lungs, which are passive in respiration, which possess in themselves no independent power of enlargement and diminution.

Different opinions were, for a long time, entertained on this subject; it was supposed that a space filled with air, separated the lungs from the containing cavity. A frequent and careful performance of the dissection mentioned above, has however shewn the lung always in contact with the pleura, when the latter has not been injured; and the chest has been opened under water without a single particle of air escaping. Indeed it is only by this contact that the function of respiration can be explained, if we admit the passive nature of the lung: the expansion and contraction of the chest would be no longer attended with enlargement and diminution of the lung, if air were contained between this viscous and the sides of its containing cavity.

All the preceding observations apply to the natural state of the parts, in which the bag of the pleura is entire; if that be wounded, so as to make a communication between its cavity and the external air, the lung no longer continues in contact with the sides of the chest. It has been almost universally received, that when an opening is made into the thorax

thorax in the living subject, the lung falls from the sides of the cavity, becomes diminished in size, or, in technical language, *collapses*, and remains motionless. Such is the representation given by Haller (*Element. Physiol. lib. viii. sect. 2. § 6.*) If an extensive wound be made on both sides, it seems generally admitted that the lungs are rendered motionless, that respiration stops, and the animal dies. But it is not equally clear that a small wound is attended invariably with collapse and a fatal termination. Cases are recorded, in which penetrating wounds of the chest have been attended with protrusion of the lung—a state apparently the direct reverse of collapse. And Mr. Norris, who had met with such an instance, opened the thorax in sheep, on one and both sides, sufficiently to enable him to introduce a finger. Respiration was not rendered difficult. (See *Memoirs of the Med. Soc. of London, vol. iii.*) Thus it should seem that the size of the wound influences the result of the experiment in a living animal; which is not irreconcilable to the representation we have already given of the passive state of the lung. For the surface exposed to the external pressure of the atmosphere by a small wound may not counteract the effect produced by the contact of the two pleurae in the whole of the rest of their extent. In all these experiments the wound should be carefully kept open, if we are to derive any instructive inferences from the result: if its sides are allowed to come in contact, no collapse of the lung could be expected. We do not know how to explain the protrusion of the lung from wounds.

If a wound be made in the lung, when there is no communication between the thorax and the external air, as by a broken rib, air escapes into the thorax, and cannot pass out: a collapse of the lung is a necessary consequence. This is what occurs in emphysema, and occasions the difficulty in breathing; the air also escapes through the wound of the pleura into the cellular substance of the body.

When a wound is made into the chest, in the dead subject, the lung, which was before in contact with the pleura, immediately recedes from it. The separation is more marked in front, less at the sides; and at last the lung, much diminished in volume, lies against the back of the chest. Of course an empty space is left, proportioned to the collapse of the lung, and the pleura is stretched over this, with a whitish opaque appearance. This experiment never fails, except when the lung is adherent. The air contained in the chest at the time of death is cooled as the rest of the body grows cold; its volume must be diminished, and the lung containing it must undergo a corresponding diminution, by virtue of its contractility of tissue. Hence a tendency to the formation of a vacuum ensues, in consequence of which the pressure of the external air pushes the diaphragm strongly upwards, and makes it very concave towards the abdomen. This is the condition in which that muscle is constantly found in the dead subject, although we might suppose that the weight of the thoracic contents, pressing on it above perpendicularly, would drive it downwards when it is no longer supported by the abdominal viscera below. If a small opening be made in it penetrating the chest, it immediately sinks, and a space is created above it by the atmospheric air entering the cavity.

How is the collapse of the lung in the dead subject to be explained? Are we to conceive that air escapes through the glottis when the lung sinks in consequence of an opening in the chest? On this supposition the organ must previously have been maintained by its contact with the sides of the cavity, in a state of greater distention than it would exhibit if left to itself. The access of the air to the thorax enables the lung to pass into its natural state, by allowing its con-

tractility of tissue full scope for exertion. But we have ascertained that the phenomenon, called collapse of the lungs, takes place in the dead body, when a ligature is placed on the trachea, so that the contractility of tissue cannot operate. It depends entirely on the sinking of the diaphragm, which gives way towards the abdomen, and is followed by the lung. The latter organ therefore is not diminished in size, and cannot with any propriety be said to have suffered collapse. Let it be remembered that the concavity of the diaphragm is maintained by the pressure of the atmosphere, forcing it into the chest, to fill the space left by the gradual diminution of volume of the lung consequent on the cooling of the air, and its contractility of tissue; and that this arises entirely from the accurate mutual contact of the lung and thoracic cavity. When the latter is exposed, the air presses on the lung at the situation of this exposure above, as much as it does against the diaphragm below, and these two organs consequently take that position which their weight and connections, independently of any other cause, would determine. We believe that the contractility of tissue of the lung has been exerted nearly to its full extent, before the chest is opened, and that it would be exerted to the utmost extent, if the diaphragm could be forced up sufficiently to fill all the space left by the contraction of the organ. It seems to us that the lung does contract after the chest has been opened, and consequently that the diaphragm is not capable of filling all the space which the contractility of the lung might leave. Bichat refers the collapse of the lung in the dead subject entirely to the cooling of the air contained in this organ after death. This, he says, produces a vacuum between the lung and the pleura costalis; the lung collapses before the chest is opened, because the air-cells contract in proportion as the air is condensed. The assertion that a vacuum exists is contrary to all observation; indeed this thing is obviously impossible. If we understand him rightly, he denies that the collapse takes place on opening the chest. "Thus," says he, "there is this difference between opening a dead and a living body: in the former the lung has already collapsed; in the latter it collapses at the instant of the opening. The contraction of the cells, when the cooled air is condensed and occupies less space, is an effect of the contractility of tissue, which remains in the organs to a certain degree after death. Moreover, if the lung collapsed in the dead body at the moment of opening the chest, the current would be in the pressure of the external air, which would expel through the trachea what was contained in the organ. But if, in order to prevent the exit of the air, you close the trachea, and then open the chest, the lung is found in the same state of collapse; therefore the air had quitted it already. Make the same experiment on a living animal, and you will always prevent the collapse of the lung." *Recherches sur la Vie et la Mort, p. 193, note 1.*

It remains for us to advert again to the serous secretion which moistens the surface of the pleura. Is this secretion necessary to the phenomena of respiration? Is that function sensibly impeded, when the serous fluid is no longer produced, and the pleura pulmonalis and costalis are united together throughout? For a long time the affirmative of this question has been maintained, and it has even been usual to attribute habitual difficulty of breathing to adhesions between the lungs and pleurae. Yet the following considerations render this supposition very doubtful. 1. It has been clearly proved, that in the healthy state the lungs and the containing cavities are perfectly contiguous, both in inspiration and expiration: reasoning alone might have shewn this. What end do the movements of the chest serve, if the lungs possess in themselves an independent power of motion?

Since, then, the lungs and chest always move together, how can there be an empty space between them? and if there can be none, how can an accidental union obstruct the motions? 2. Adhesions between the pleura pulmonalis and costalis are extremely frequent. They are found, not only in individuals who have died after a long disease, but also in those whom a violent death has surprised in a state of health. In many instances the whole surface of the lung adheres to its cavity: yet in general the individuals have enjoyed perfect freedom of respiration. We must therefore conclude, that a continuity of surface between the lungs and chest does not injure the freedom of the respiratory functions. The utility of the serous fluid does not then appear so clear to us in the pleura, as in other cavities of the body. In the respiratory apparatus, the motions of the sides of the cavity and of the contained organs hold a certain necessary and invariable relation to each other. The brain tends to move in an immovable bony case; the gastric viscera may change their position and relations to each other, without any alteration in the abdominal parietes: in the synovial cavities there are two surfaces constantly moving in an inverse direction to each other, &c. We every where see the different portions of a serous surface sliding on each other in a more or less marked degree, and we naturally conclude that the presence of a fluid is indispensable to that motion. The thorax alone presents to us two serous surfaces always in contact at the same points.

The *two lungs* occupy the serous cavities on the sides of the chest, lined, as already described, by the pleurae. They are separated from each other by the mediastinum, but united by the circumstance of their receiving from two common trunks (the trachea and pulmonary artery) the air and blood which are necessary to their phenomena. They are not symmetrical, but differ both in size and form, exhibiting the irregularity which belongs to the organs of the organic life; or rather holding a middle place in this respect, as well as in their functions, between those and the organs of the animal life. The heart, which is turned to the left, and placed almost entirely on the left side of the chest, diminishes the transverse diameter of the corresponding pleura: the liver elevates the diaphragm very sensibly on the opposite side, so as to reduce the perpendicular measurement of the right pleura. Hence the left lung is the longest, and the right the broadest of the two.

Their volume, in the natural state, is always exactly the same as the capacity of the bags of the pleurae: their external surface is constantly in contact with these cavities. As they have no power of motion in themselves, and follow every change which the sides of the chest undergo, their capacity is constantly varying: when the chest is enlarged, they are dilated by the entrance of air into their substance through the trachea, and when it is contracted, they undergo a corresponding diminution by the expulsion of air. For further explanation and proofs on this subject, see the account of the pleura. Yet we cannot always judge of the volume of the lungs by the apparent extent of the pectoral cavity: the heart differs considerably in size, and similar variations of the liver, influencing the height to which the diaphragm ascends, are still more common. The collapse of the lungs, which we have considered in speaking of the pleura, is less marked when these organs are distended with blood: it is generally less in children than in adults, and does not take place at all in the conversion of these organs into a solid mass like the liver, at least in the parts immediately affected. Thus the bulk of the lungs depends more on the fluids which they contain, particularly the blood and air, than on their solid substance. They are dilated in in-

spiration; but still thoroughly penetrated with air in the most complete expiration. Long and continued compression or extraction of the air by an exhausting syringe reduces them to so small a bulk, that they do not equal one-fourth of the cavity which is designed to contain them. Preternatural accumulations of fluid, as water or pus, diminish the size of the organs in the same way during life. The most numerous incisions and the strongest pressure will hardly get rid of all the air from the lungs: if we cut a very small portion, and squeeze it most forcibly, there is still enough air to keep up the fire beyond what the solid matter would cause, and it still swims in water. In short, this air can be completely got rid of only by ebullition, maceration, or means that entirely destroy the texture of the organ.

The lungs generally contain more blood after death than during life, as an accumulation takes place in their vessels in the act of dying: the quantity of this fluid influences the bulk of the organ, when the cavity of the chest is exposed. When there is much blood, incisions into the lung produce a less marked diminution of volume than we might expect: they only give issue to the air and not to the blood. The ready escape of the air, too, requires a free communication of the air-cells with each other, which the stagnation of the blood prevents, by confining the air in every part, so that only the cut portion is evacuated by the incisions. Where the individual has died of hemorrhage, the lungs are almost entirely free from blood, and owe their volume to the air: here superficial incisions produce a sudden and marked collapse. This has been particularly observed in persons executed by the guillotine: three or four incisions have speedily reduced the lung to nearly the half of its original size. (Bichat, Anat. Descript. t. iv. p. 12.) For the same reason, the degree of collapse of the lung will be much influenced by the quantity of mucous fluids contained in the air-vessels and cells of the lungs.

The lungs are the lightest organs in the body; they constantly swim when immersed either entire, or in parts, in water. This property depends obviously on the same cause as their volume, namely, the air which they contain. When entirely deprived of this fluid, and reduced to their own substance, they do not swim. This is seen when one of them is so compressed and flattened by the effusion into the chest of a large quantity of fluid, as to serve no longer for the purposes of respiration. In certain diseases, too, the lung is rendered solid and impervious to air, and then sinks in water; but this is a pathological phenomenon. Immersion in water is, therefore, the ordinary and best method of determining the specific gravity of the lung. The greater or smaller quantity of blood which may be contained in their vessels at the time of health occasions them to vary in weight when compared in different subjects.

There can be no doubt that the lungs of a person, who has died of asphyxia, are heavier than those of one who has perished from hemorrhage: and that these organs will be lighter after a chronic disease, which has exhausted the vital powers, and diminished the energy of the circulation, than after strangulation, in which there is a considerable afflux of blood into them to the last moment.

The form of these viscera is in general conical, with the basis downwards, and the apex upwards. This form is tolerably constant, because it depends on that of the thorax, which varies little in its natural state. They correspond immediately to the solid sides of the chest only at the upper and outer parts: on the inner side they lie against the heart, and below are separated from the abdominal organs by the diaphragm: in the two latter aspects, therefore, their form is influenced by that of the neighbouring parts. The heart, placed

placed chiefly on the left side of the chest, leaves a much narrower space for the basis of the left than for that of the right lung. The natural or accidental varieties in the form of the chest, as curvatures of the spine, with the concomitant deviations in the figure and direction of the ribs, are always attended with corresponding varieties in the lungs. We may describe in each lung, besides the basis and apex, two surfaces, an internal and external.

The external surface is convex in its whole extent, and corresponds to the thoracic parietes, from which it is separated by the pleura costalis; it is smooth and polished, and lubricated by a serous exhalation. A considerable groove is observed in it, beginning behind a little below the apex, and running obliquely forwards and downwards to the basis. This groove runs throughout the substance of the lung, which it divides into two nearly equal halves called lobes: these are connected together at the root of the organ by the reflexion of the pleura, and by receiving their blood-vessels from a common trunk. The two lobes are in contact with each other by broad and flat surfaces, which are smooth and lubricated, like the external surface of the lung, as they are covered throughout by the pleura. The upper lobe of the right lung is marked by another groove, directed obliquely from above downwards, and within outwards; so that its mass is divided into three lobes: the middle is the smallest, and triangular in its figure. This secondary groove is more variable than the former in its existence, its length and depth. Sometimes, but very rarely, it is not found; and it is often incomplete, so as not to divide the middle lobe entirely from the superior. It is very seldom seen in the left lung.

The internal surface is nearly plane, and divided into two unequal portions by the insertion of the bronchi and pulmonary vessels, which takes place towards its upper and back part.

It is at this point, which is called the root of the lung, that the pleura is reflected over the organ: here, therefore, the pleura pulmonalis and costalis are continuous. This is the only situation in which the lung adheres to the containing cavity; the surface is free and unattached every where else; it is sometimes called, from this circumstance, the *ligamentum pulmonis*.

The bronchus, the pulmonary artery and veins, the nerves and lymphatics of the organ, surrounded and connected by cellular substance, and forming a single large fasciculus, pass out of the mediastinum to the lung. The pleura is reflected over this fasciculus, covers it, and is continued over the lung. That portion of the inner side of the lung which is behind the root is narrow, and corresponds to the lateral surface of the vertebral column: the anterior division is broader, and is contiguous to the heart and pericardium; it is slightly concave at this part. Above and below the insertion of the vessels the inner surface of the lung is not divided into these two parts.

The external and internal surfaces of the lung are united by two edges. The anterior is thin, particularly below, irregular in its outline, directed obliquely downwards and forwards, and has in the left lung a small notch corresponding to the apex of the heart. The posterior is obtuse, not clearly marked, directed vertically, and corresponding to the hollow at the angles of the ribs. On the latter is seen, above, the commencement of the great groove, which divides the lung into two lobes.

The basis of the lung rests on the diaphragm, and is concave, to suit the convexity of that great muscular partition. It is directed obliquely from within outwards, from above downwards, and from before backwards; corresponding in this respect entirely to the diaphragm. The concavity of

the basis is more marked in the right than in the left lung, on account of the greater convexity of this side of the diaphragm produced by the liver. The termination of the great groove is found on this surface of the organ, so that the two lobes are distinct here as well as in other situations; but the superior lobe contributes to the formation of the basis only in a very small part of its extent, particularly on the right side. The circumference of the basis presents a thin edge, with a rather irregular outline interposed between the ribs and the diaphragm, near the attachment of the latter. This is more sensible on the right than on the left side.

Its appearance varies according to the different states of the lungs; the preceding description applies to the dead subject. In inspiration, the diaphragm descends and becomes nearly plane; the lung follows it, and assumes a corresponding figure, its edge, instead of being thin, becoming thick, and no longer included between the diaphragm and ribs.

The apex of the lung is small and obtuse, and corresponds to the cul-de-sac of the pleura under the first ribs. In this way it is completely insulated from the lower part of the neck. It exhibits several more or less marked tubercular ringings.

The whole surface of the lungs is unconnected to the cavity, except in the situation of the *ligamenta pulmonum*. The opposed surfaces of the lobes are in the same way unconnected to each other, and covered by the serous membrane. All these parts are moistened by a serous exhalation.

The colour of the lungs, when not influenced by that of the fluids which they contain, is extremely pale; sometimes a slight tawny brown, but more frequently grey or ash-coloured; and sometimes completely white. This colour is seen over the whole organ, both on its surface, and in the interior, when it is quite free from blood; but is no longer visible when the lung is loaded with that fluid. Hence we understand why we meet with it so seldom in the dead body, since a distention of the pulmonary vessels with blood is one of the most ordinary phenomena of death. The only cases in which we can expect with some certainty to find the lungs exhibiting this pale colour throughout, are those of deaths from hemorrhage. It was noticed by the French in individuals who perished by the guillotine. We may often observe it in some particular points of the organ, where the absence of blood may be ascertained by incisions. The tawny or greyish colour of the lungs is interrupted by small black or brown spots, irregularly disseminated over the surface, and very variable in number and form. Often the organ is very thickly spotted in this way; at other times they are scattered here and there at considerable distances; sometimes, but very seldom, they do not exist at all. These spots do not depend in the least on the blood. Simple inspection is sufficient to prove that they belong to the organization of the part. They are very distinct in the palest and most bloodless lungs, and may be easily recognised in the general livid tint of those which are most loaded; they seem to possess always the same intensity of colour; and they are always circumscribed, while the marks arising from the blood end imperceptibly. These black spots present every variety of figure. Some are superficial, others extend into the substance of the lung, and some are found in the interior of the organ. They seem to belong entirely to the pulmonary tissue, as they are never seen on the bag of the pleura, and are found in the substance of the lung.

But generally the lungs are loaded with blood at the time of death, and do not consequently exhibit the paleness which we have described as belonging to their proper tissue. They are usually livid, violet-coloured, brownish, or reddish; and the

mixture of these various tints gives them the marbled appearance, which has generally been regarded in dissecting rooms as the natural state of the organs, although it is merely produced by death. The brown, black, or violet colour is the most frequently observed, and occupies the lung most extensively. It depends on the presence of venous blood, which stagnates as soon as respiration has ceased to colour what the right ventricle still impels. The tint varies as the blood is accumulated more or less in particular situations. The highest degree of this congestion produces the black observed in the lungs of those who die of asphyxia; the brown or violet colour is caused by a slighter degree of the same effect. The colour is always the deepest in the most depending part of the lung, as the blood, obeying only the laws of gravity after death, settles in the lowest parts. From the ordinary position of the body this deep colour is usually seen at the back of the lung; but if the subject be laid on the face, the same phenomenon is exhibited in front. These dark colours are not the only ones observed in the lungs; more or less extensive patches of a bright red are often seen; this may occupy a large portion of the organ, while the rest is brown or violet-coloured. This red colour is universal in the lungs of children, which do not present the black spots; the former gradually disappears, and the latter increase with the progress of age. The same bright tint extends into the substance of the lung. We are at a loss for a satisfactory explanation of this appearance: if it arose from the blood being acted upon after death, by the air contained in the pulmonary air-cells, we should expect to find it more universal and more frequent. The parts of the lung, however, in which this tint is observed, certainly contain scarlet blood, and owe the colour to that.

The lungs are the least dense, and least resisting of all organs formed of solid tissues. They yield readily to compression, preserve the mark of the pressure, and are restored imperfectly to their original state. This observation applies only where they are not loaded with blood, but contain merely that quantity of air, which never leaves them after they have been once distended with it. When full of blood, they acquire a consistence foreign to their own substance, resist pressure more effectually, and restore themselves more readily. Hence softness and flaccidity more particularly characterize the lungs of persons who have died of hemorrhage. When we squeeze the air forcibly into a part of the lung, a peculiar crackling noise is produced by the bursting of the air-cells: this crepitation does not take place in diseased lungs.

The softness of the pulmonary texture arises from the lungs being entirely composed, as we shall see presently, of various vascular systems. It accords very perfectly with the passive part that they perform in the respiratory phenomena: possessing no power of motion in themselves, they expand and contract merely in consequence of motions of the chest.

The lungs are composed of a cartilaginous and membranous tube, by which air is conveyed into them; of the pulmonary artery and veins, of which the former terminates the system of black blood, and the latter commence that of red blood; of the bronchial vessels concerned in the nutrition of these organs; of a peculiar tissue, composing a congeries of minute cells, which receive the air admitted in respiration; and of lymphatics and nerves. These parts are all united by cellular tissue, and covered externally by the reflected pleura.

The air-vessels compose the essential part of the lungs, with respect to their functions as organs of respiration. They introduce the fluid by which the blood is changed;

this process goes on at their surface; and the air, after serving the purposes of respiration, is expelled through them. When taken altogether they form the cavity of the respiratory apparatus, which is analogous to that of the digestive canal, in having a mucous lining, but differs in its arrangement, as it is subdivided into a vast number of canals, decreasing successively like arteries. These are the only tubes in the body constantly open; it is necessary that the air should have free and constant access to them. This order of tubes is begun by a single trunk, which unites the two lungs, and necessarily renders their phenomena simultaneous. The common trunk is called trachea (*aspera arteria*, *trachée artère*); and its primary divisions the right and left bronchi.

The *trachea* is placed in front of the vertebral column, extends from the upper part and middle of the neck to the upper part of the chest, beginning immediately below the larynx, and ending about the level of the second or third dorsal vertebra. It is placed on the middle line of the body, and is symmetrical in its whole extent; in this respect it approaches to the external organs: the symmetry ceases in its divisions. It appears cylindrical in front, but is flattened behind. Its diameter varies according to the age of the subject, and the natural volume of the lungs; it may be about eight or ten lines in the adult, and is exactly the same with that of the larynx, measured at the cricoid cartilage. It continues the same through the whole length of the trachea.

In front it is covered above by the two portions of the thyroid gland, which unite together at the middle of the tube. Lower down the sterno-hyoidei and sterno-thyroidei, and the inferior thyroid veins cover it. In the chest it is enclosed in the posterior mediastinum, and corresponds to the thymus, to the left subclavian vein, the *arteria innominata*, and the arch of the aorta. Behind it covers the oesophagus, and towards the right the vertebral column. On the sides it is covered above by the lateral portions of the thyroid gland, and is contiguous below to the common carotids. A loose and abundant cellular tissue forms the medium of its connection to all these parts. The superior extremity is connected to the cricoid cartilage by a ligamentous substance; the inferior is placed at the right side of the descending aorta, is bifurcated, and produces the two bronchi. The latter begin about the second or third dorsal vertebra, and separate from the common trunk nearly at a right angle, yet they go with some obliquity, downwards and outwards, each to its corresponding lung. Here we begin to meet with the irregularity of form that characterizes the organs of the internal life. The left bronchus is smaller than the right, and takes a much longer course: it passes under the arch of the aorta, while the other goes immediately to its lung. These tubes enter the lungs at the situations already described as the roots of those organs. They ramify in every direction, and divide into branches, becoming successively smaller and smaller. These subdivisions are so numerous, that every part of the lung contains them. The exact manner of their termination is not understood.

The air-tubes are composed of three parts, an exterior membrane, of a fibrous and probably muscular texture; a cartilaginous structure, which is united to the preceding; and a mucous lining. The exterior membrane rises above from the circumference of the cricoid cartilage, and occupies the whole extent of the trachea and bronchi; forming a very essential part of those tubes. It is tolerably thick in the greatest part of its course, but grows thinner in the smaller ramifications of the bronchi, where it cannot be easily traced. It is formed of parallel and closely arranged longitudinal fibres, the nature of which is doubtful; some consider

consider them as muscular, others regard them as a fibrous organ, to which their appearance is very similar. This membrane alone constitutes the solid portion of the trachea behind; and hence arises the flattened figure of the tube at that part. This peculiarity in the back of the trachea has been referred to the situation and motions of the diaphragm, which lies close behind it: but the same structure exists in the bronchi also, where it cannot admit of that explanation. The arrangement is different on the anterior part and sides of the trachea, in two-thirds at least of the circumference of the tube. The fibrous membrane is interrupted by portions of cartilage (anuli cartilaginei), which keep it on the stretch, and thereby preserve the air-tubes constantly open. Each of these cartilages represents two-thirds of a circle. They are bent on themselves, flattened on their surfaces, uniform in length, but of different breadths. Their convexity forms a part of the exterior surface of the tube; their concavity corresponds to the mucous membranes, from which a thin cellular stratum separates them. Their superior and inferior margins are rounded, continuous on the outside with the fibrous tissue, and slightly prominent through the mucous membrane on the inside. Their extremities project more or less behind in the fibrous tissue, are all on the same level, are rounded, and a little bent upwards. They vary in number from about sixteen to twenty; they may be more or less broad; and, as the length of the tube is nearly uniform, they must be more numerous in proportion as they are narrower. In general, they are broader in front, and diminish progressively to the back part: but the reverse of this sometimes happens; or two may be united at their edges. Commonly their direction is horizontal to the axis of the trachea; but many of them are often more or less oblique.

In colour and texture they resemble the fibro-cartilages of the organs of sense: they are very elastic.

The first cartilage is generally much larger than the succeeding ones; the last has a prolongation from its middle corresponding to the bifurcation of the bronchi.

In the ramifications of the bronchi the cartilages become less regular in their form, and fewer. They no longer exhibit that annular form, but consist merely of small pieces, sometimes separate, and sometimes united. As the subdivisions are multiplied, the cartilages become less firm, and at last disappear altogether, so that we find only a membranous structure when we have traced the air-tubes as far as the eye can go.

The external surface of this fibrous membrane is sprinkled behind with small lightish brown and flattened bodies of very variable figure, round, oval, &c. These are mucous glands, of which the excretory ducts open on the internal surface of the tube. They are smaller on the bronchi than in the trunk of the trachea, and they become more minute in proportion as the vessels ramify. Their structure seems to be very simple; one duct comes from each gland generally; but sometimes two or three glands are united, and there the ducts are more numerous. The fibrous membrane exhibits none of these glands in the intervals of the cartilages, on its external surface. The inner surface of the membrane, in the same situation, corresponds to the mucous lining of the tube, from which it is separated by numerous small and closely arranged granular bodies, which are probably mucous glands. At the back part of the tube there is found, under the fibrous membrane, a stratum of transverse fibres extended between the extremities of the cartilages, to which they are attached. These are disposed in small fasciculi, have not the white aponeurotic appearance of the fibrous membrane, and seem to be real muscular fibres. They are connected

to the mucous lining by a loose cellular tissue, and may be most advantageously seen by dissecting away that membrane from the inside. In what manner these fibres affect the phenomena that occur in the trachea we do not know. The longitudinal ones, that compose the fibrous membrane already described, have generally been regarded as of a muscular nature: but their appearance by no means warrants this representation. They possess considerable elastic power, so that the trachea, when extended, recovers itself very quickly and completely: this property is frequently brought into exercise in the living state from the motions of the head and neck. The effect of the cartilaginous semi-circles, which are incorporated with this membrane, in preserving the air-tubes permanently open, and the necessity of this arrangement to the execution of the respiratory functions, are too obvious to require any detailed illustration.

The mucous membrane, or the third constituent portion of the air-tubes, is the second division of that great mucous apparatus, called by Bichat *gastro-pulmonaire*. We trace its continuation from the pharynx into the larynx, through that cavity into the trachea and bronchi, to their ultimate ramifications. In the latter, it is said to exit alone, or without the other two parts already mentioned: but the minuteness of the parts makes it difficult to ascertain this point by direct examination, although such a structure would be favourable to that more intimate connection between the blood and air-vessels, which is necessary to the chemical phenomena of respiration, according to the notions commonly entertained respecting these phenomena. The external surface corresponds behind to the transverse fibres; and in the rest of its extent to the fibrous membrane and cartilages, which latter project through it. The connecting medium which attaches it to all these parts is a cellular substance, admitting easily of separation. The internal surface is smooth, and constantly lubricated by a mucous secretion: it forms the cavity of the air-tubes. The excretory canals of the mucous glands open on it in many parts very distinctly. In the back of the tube, where there is no cartilage, it exhibits numerous prominent and regular longitudinal folds: these extend into the bronchi and their ramifications. They are not produced by the contraction of any parts situated exteriorly, but exist when the membrane has been detached, and are not affected by transverse extension of the tube: they seem to arise from small fibrous columns forming a part of the structure of the membrane.

For the organization of this membrane, we must refer to the general view exhibited in the article MEMBRANE. It is thinner, less spongy and soft, and more firmly attached in the trachea than in the larynx: the orifices of the mucous ducts are also smaller; in the bronchi it is still more delicate, and this thinness increases as the tubes divide. In the natural state it is white, so as to indicate that the capillary system is not very clearly marked in it. These vessels are developed and become perceptible under numerous circumstances, particularly in catarrhal affections, to which the pulmonary mucous membrane is very subject. The blood is then accumulated in the capillaries, and gives to the membrane a red colour, which it does not possess naturally.

It is supposed that this membrane composes entirely the air-cells, or vesicles of the lungs, in which the minute ramifications of the air-tubes end. If we impel air into the trachea, the whole lung becomes distended, and increases in volume in proportion to the quantity of air inflated. Attentive observation will then convince us that its whole substance is composed of small cells, which we can readily discern on the surface. If the inflated lung be dried, or if the organ be distended with spirit of wine, and then cut, its whole

whole substance is found to be composed of these cells, as well as its external surface. Injection with quicksilver will demonstrate the same structure. This gives to the lung, when cut or torn, a porous and spongy appearance throughout. The cells, when attentively surveyed on the surface of the lung, have a roundish figure, but their outline is often irregular. When inflated they measure $\frac{1}{16}$ th or $\frac{1}{8}$ th of a line in diameter. They communicate together in all directions so completely, by the ramifications of the air-tubes, that air might pass easily from a single cell into all parts of the lung; but the cells of the neighbouring lobules do not seem to have any direct communication.

The mucous membrane, in an extremely delicate state, continued from the minute ends of the air-tubes, is supposed to compose these cells; but the minuteness of the objects renders our description of them, excepting a few general facts, rather uncertain. Anatomy discovers to us rather a spongy net-work, filled with air, and formed by blood-vessels crossing in every direction, than any clear arrangement of distinct cells, connected to the bronchial ramifications, like grapes to their stalks, as they have been described and drawn by several anatomists.

In this view of the subject, the extent of surface of the mucous membrane must be enormous. Many attempts have been made to express it in numbers. Hales makes the air-cells $\frac{1}{16}$ th of an inch in diameter; the surface of the air-tubes equal to 1035 square inches; and that of the air-cells to 20,000. Keil estimates the number of the vessels at 174,418,615, and the whole internal surface of the lung at 21,906 square inches. Lieberkuhn carries his estimate of the surface as high as 1500 cubic feet. We mention these circumstances only to shew the great extent of the mucous membrane, and not because we place much faith in their accuracy. In reading descriptions of the minute structure of the lungs, and, indeed, in all other analogous parts of anatomy, we should always bear in mind the observation of Haller; "*Ea fere hominum est infelicitas, ut omnis ultima rerum physicarum historia parum firma sit, et ut altera illa, rerum gestarum memoratrix, in mythices fines terminatur.*"

A mucous fluid constantly lubricates the whole of this surface. It is limpid, mild, and nearly insipid, or slightly salish, and but little tenacious in the natural state. When free from air, it sinks in water. It is produced in so small a quantity, that it seems to be dissolved in the air, and thus to pass off insensibly in expiration, or to be taken up by the absorbents. It is poured out much more abundantly under various circumstances, and is altered in colour and consistence: it is then expelled by the expiratory efforts which constitute cough. In children it has a reddish colour; and it is often rather livid in adults.

The watery vapour discharged from the lungs in expiration concurs in lubricating the surface of the air-passages. Whether there be any exhalation from the general mucous surface, in addition to the mucous secretion, seems a point hardly susceptible of positive determination.

The pulmonary mucous membrane is the part in which the chemical phenomena of respiration are carried on; its surface is in contact with the air taken into the lungs. The latter fluid is the only one, in addition to its natural mucus, of which it can bear the contact. All other substances, even the clearest water, are immediately and powerfully rejected by it. In itself it possesses no power of expelling any irritating matter from its surface; but it excites the expiratory muscles which act convulsively and repeatedly until the cause is removed.

The vessels and nerves of the lungs are principally distri-

buted on the air-tubes, of which they every where follow the course. The arteries of the trachea come from the inferior thyroidal; those of the bronchi are derived immediately from the aorta, and are called the bronchial arteries. The latter ramify in conjunction with the air-tubes, and adhere closely to them: they are distributed chiefly on the internal membrane. Several branches are spent on the bronchial glands, and on the parietes of the pulmonary vessels. Do they anastomose with the pulmonary artery? We should be inclined to suppose that they do not, from considering that the two kinds of vessels contain blood of different natures, and have altogether different offices. The bronchial arteries convey arterial blood for the nutrition of the lung; the pulmonary artery takes the venous blood, that it may be submitted to the action of the air in respiration. Yet it has been asserted by several anatomists, that such an anastomosis does take place. The bronchial veins accompany the arteries; their trunks end in the vena azygos on the right side, and in the superior intercostal vein on the left.

The par vagum furnishes nearly all the nerves belonging to these organs: those of the trachea come from it altogether. The nerves of the bronchi are derived from the pulmonary plexuses formed principally by the par vagum, but partly also by branches from some ganglia of the great sympathetic. As these nerves seem to be distributed entirely on the air-tubes, perhaps the epithet bronchia would be more proper for them than pulmonary.

The vascular system of the lungs may be divided into three parts, distinct in their nature, properties, and the immediate object of their phenomena. The first is the pulmonary artery, or the end of the general system of black blood; the second, the pulmonary veins, or commencement of the general system of red blood; and the third, the capillary system intermediate to the two preceding. (See CIRCULATION AND HEART.) The pulmonary artery arises from the upper and anterior part of the right ventricle, in front of the origin of the aorta. It passes upwards and backwards, lying close on the left side of the root of the aorta, and, after a course of about an inch and a half, divides into a right and left branch destined for the corresponding lungs. These two divisions separate most widely at their origin, going off from the trunk at right angles, and hardly forming a sensible angle with each other. The separation takes place on the left side of the aorta. The right trunk goes immediately behind the aorta and superior vena cava, and follows a transverse course to the right lung; the left has an analogous course on the left side of the body, but is much shorter than the right, on account of the latter passing behind the aorta and vena cava. Both are placed in front of the bronchi, and cross the course at first, being directed a little from below upwards; but they are subdivided exactly like the bronchi, and follow their course, being closely connected to them throughout: the artery is generally placed above its corresponding air-tube. For the organization of this vessel, we refer to the article HEART.

The pulmonary veins, arising from the capillary system, follow a course analogous to that of the arterial divisions. These also accompany the air-tubes, and are situated under them. They unite gradually into larger and larger tubes, and form ultimately four considerable trunks, two belonging to each lung, and terminating in the left auricle of the heart. The superior right pulmonary vein passes out of the lung below the bronchus, and goes with a little obliquity downwards: the inferior ascends obliquely towards the auricle. The left veins have a similar arrangement; one descends, and the other ascends: they are more approximated than on

the right side. For the organisation of these vessels, see HEART.

The capillary vessels of the lung are distributed in infinite number through all parts of the organ, of the proper tissue of which they compose a very considerable share. As they have no connection with the nutrition of the part, and perform no secretion, they give passage only to the blood, and are hence remarkably distinguished from the general capillary system. These vessels cover in vast profusion the air-cells of the lungs; so that when they are injected with coloured fluids after death, the whole substance of the organ appears dyed of the peculiar colour. In them the blood is exposed to the air, and converted from the dark or venous into the red or arterial state.

The substance of the lungs, on superficial examination, offers a soft spongy mass, yielding easily to pressure, and restoring itself afterwards to its original state in an imperfect manner. When we view it more attentively, we observe on the surface small whitish lines circumscribing spaces of different figures, as triangular, quadrangular, &c. These are called lobules of the lungs, and vary considerably in size as well as figure. They are again divided into other smaller parts. These lobules are all connected together by a loose and soft cellular substance, which never contains any fat; and the same substance unites the reflected pleura to the external surface of the lung. If we tear the substance of the organ, and inflate it, the air fills the cells of this cellular texture, and makes it more sensible: it is also in some cases rendered more obvious, by being the seat of a watery deposition, which constitutes anasarca of the lungs. Its cells have no communication with the air vesicles, unless the latter be broken by inflation, as when we squeeze the air in them forcibly, they crack, and the air escapes into the cellular texture, uniting the lobuli. On the other hand, we might inflate the cellular substance distinctly from the air-cells.

Each lobules of the lung consists of a branch of the air-tube with a corresponding proportion of cells, a branch of the pulmonary artery and vein, a portion of the pulmonary capillaries of the bronchial vessels and nervous ramifications, connected by the cellular substance already described.

The lymphatics of the lungs are numerous, and divided into a superficial and deep-seated set: the former constitute a net-work on the surface of the lung, and communicate also with the latter. They pass through numerous glands, called bronchial, placed on the trunks of the air-tubes and blood-vessels, partly within, but chiefly without the substance of the lung. Other larger glands are situated about the division of the trachea, and the absorbents of the right and left lung communicate in them. Some absorbents of the right lung terminate in the right absorbent trunk; the rest, with those of the left, end in the thoracic duct, passing through glands on the spine.

The bronchial glands are large in size, and numerous in proportion to the lung; but they vary in both these respects in different subjects. Several of the smallest are found on the bronchi, within the substance of the lung. Their colour is the most remarkable of their properties: in the adult it is a deep livid or black. Their consistence is rather soft, and a coloured fluid may be expressed from them, when cut or divided. It is now clearly ascertained that these bodies belong to the lymphatic system. Anatomists formerly conceived that they secreted a particular fluid, and poured it into the bronchi. We are quite ignorant of the cause of their peculiar black colour.

The lung, then, is made up of the tissues just described, covered on the surface by the very thin and transparent pleura pulmonalis, which is connected to the organ by

cellular substance, and gives it the smooth external surface.

Development of the Lungs.—The *fœtus* has no respiration: from the circumstances under which it is placed in the uterus, it must obviously be altogether precluded from exercising that function; but it begins immediately after birth: hence the lungs, formed nearly as soon as the principal organ of circulation, possess, at a very early period, a considerable development and well-marked form. Their organisation, too, is perfect, or at least they are capable of executing their functions, before the time at which they naturally come into action: for there are instances of children born long before the end of the ninth month, as, for instance, at the seventh, or even sooner, who have been preserved alive by great care. In the early periods their colour is reddish; they then assume a slightly tawny hue, which is continued till the time of birth, and is not even changed by respiration, although the admission of air into the organs at that time is followed by the entrance of a larger quantity of blood.

The lobuli are very distinct in the *fœtus*, and easily separable: the connecting substance appears to be more copious. Although the lungs are small in a *fœtus* at full time, compared to those of a child who has breathed, we cannot say, as some anatomists represent, that they are extremely diminutive, and confined to the back of the chest. As they are at this time entirely free from air, they possess a density, which makes them sink instantly in water, when plunged into it either entire or in slices. They are penetrated by much less blood than after breathing has begun, and therefore reduced almost entirely to their solid and organised contents: they form at this time about $\frac{1}{10}$ th of the weight of the whole body.

As the function of respiration, which commences at the moment of birth, goes on afterwards uninterruptedly, and as the phenomena are as regular and perfect at this time as in more advanced age, we have no reason to expect that the intimate structure of the organ, that is, the arrangement of the different component tissues, will be different at that age from what we know of it in the adult: but the vascular trunks belonging to these parts exhibit some peculiarities, of which the details will be found in the articles HEART and CIRCULATION.

Breathing begins immediately after birth; the enlargement of the chest occasions the lungs to be distended with air, and consequently to become specifically lighter; a greater quantity of blood passes through them, and thus they acquire greater absolute weight. The increase of volume must be limited by the capability of enlargement in the chest; and this cannot be very considerable immediately on birth. This enlarged size is not, therefore, sufficiently marked, to be relied on as a proof that respiration has begun. It is a well-known fact, which we have already stated, that the lungs of an individual, who has breathed, swim in water, whether they be immersed entire or in slices. This is a property remarkably contrasted with what takes place under the same treatment before birth. A criterion has been sought for in this source, to determine, in doubtful cases, whether a child has been born dead or alive: and the consideration is a highly important one, from the influence it may produce on medical opinions, in cases of suspected child-murder. We shall only observe here, that the convulsive attempts to establish respiration, although not successful, may introduce air enough into the lungs to make them buoyant in water; that attempts to inflate them, in order to preserve the child, or after it has died, may have the same effect; that the disengagement of air by putrefac-

whole substance is found to be composed of these cells, as well as its external surface. Injection with quicksilver will demonstrate the same structure. This gives to the lung, when cut or torn, a porous and spongy appearance throughout. The cells, when attentively surveyed on the surface of the lung, have a roundish figure, but their outline is often irregular. When inflated they measure $\frac{1}{4}$ th or $\frac{1}{2}$ th of a line in diameter. They communicate together in all directions so completely, by the ramifications of the air-tubes, that air might pass easily from a single cell into all parts of the lung; but the cells of the neighbouring lobules do not seem to have any direct communication.

The mucous membrane, in an extremely delicate state, continued from the minute ends of the air-tubes, is supposed to compose these cells; but the minuteness of the objects renders our description of them, excepting a few general facts, rather uncertain. Anatomy discovers to us rather a spongy net-work, filled with air, and formed by blood-vessels crossing in every direction, than any clear arrangement of distinct cells, connected to the bronchial ramifications, like grapes to their stalk, as they have been described and drawn by several anatomists.

In this view of the subject, the extent of surface of the mucous membrane must be enormous. Many attempts have been made to express it in numbers. Hales makes the air-cells $\frac{1}{8}$ -dth of an inch in diameter; the surface of the air-tubes equal to 1035 square inches; and that of the air-cells to 20,000. Keil estimates the number of the vesicles at 174,418,615, and the whole internal surface of the lung at 21,906 square inches. Lieberkuhn carries his estimate of the surface as high as 1500 cubic feet. We mention these circumstances only to shew the great extent of the mucous membrane, and not because we place much faith in their accuracy. In reading descriptions of the minute structure of the lungs, and, indeed, in all other analogous parts of anatomy, we should always bear in mind the observation of Haller; "*Ea fere hominum est infelicitas, ut omnis ultima rerum physicarum historia parum firma sit, et ut altera illa, rerum gestarum memoratrix, in mythices fines terminatur.*"

A mucous fluid constantly lubricates the whole of this surface. It is limpid, mild, and nearly insipid, or slightly saltish, and but little tenacious in the natural state. When free from air, it sinks in water. It is produced in so small a quantity, that it seems to be dissolved in the air, and thus to pass off insensibly in expiration, or to be taken up by the absorbents. It is poured out much more abundantly under various circumstances, and is altered in colour and consistence: it is then expelled by the expiratory efforts which constitute cough. In children it has a reddish colour; and it is often rather livid in adults.

The watery vapour discharged from the lungs in expiration concurs in lubricating the surface of the air-passages. Whether there be any exhalation from the general mucous surface, in addition to the mucous secretion, seems a point hardly susceptible of positive determination.

The pulmonary mucous membrane is the part in which the chemical phenomena of respiration are carried on; its surface is in contact with the air taken into the lungs. The latter fluid is the only one, in addition to its natural mucus, of which it can bear the contact. All other substances, even the clearest water, are immediately and powerfully rejected by it. In itself it possesses no power of expelling any irritating matter from its surface; but it excites the expiratory muscles which act convulsively and repeatedly until the cause is removed.

The vessels and nerves of the lungs are principally distributed

on the air-tubes, of which they every where follow the course. The arteries of the trachea come from the inferior thyroidea; those of the bronchi are derived immediately from the aorta, and are called the bronchial arteries. The latter ramify in conjunction with the air-tubes, and adhere closely to them: they are distributed chiefly on the internal membrane. Several branches are spent on the bronchial glands, and on the parietes of the pulmonary vessels. Do they anastomose with the pulmonary artery? We should be inclined to suppose that they do not, from considering that the two kinds of vessels contain blood of different natures, and have altogether different offices. The bronchial arteries convey arterial blood for the nutrition of the lung; the pulmonary artery takes the venous blood, that it may be submitted to the action of the air in respiration. Yet it has been asserted by several anatomists, that such an anastomosis does take place. The bronchial veins accompany the arteries: their trunks end in the vena azygos on the right side, and in the superior intercostal vein on the left.

The par vagum furnishes nearly all the nerves belonging to these organs: those of the trachea come from it altogether. The nerves of the bronchi are derived from the pulmonary plexuses formed principally by the par vagum, but partly also by branches from some ganglia of the great sympathetic. As these nerves seem to be distributed entirely on the air-tubes, perhaps the epithet bronchia would be more proper for them than pulmonary.

The vascular system of the lungs may be divided into three parts, distinct in their nature, properties, and the immediate object of their phenomena. The first is the pulmonary artery, or the end of the general system of black blood; the second, the pulmonary veins, or commencement of the general system of red blood; and the third, the capillary system intermediate to the two preceding. (See CIRCULATION and HEART.) The pulmonary artery arises from the upper and anterior part of the right ventricle, in front of the origin of the aorta. It passes upwards and backwards, lying close on the left side of the root of the aorta, and, after a course of about an inch and a half, divides into a right and left branch destined for the corresponding lungs. These two divisions separate most widely at their origin, going off from the trunk at right angles, and hardly forming a sensible angle with each other. The separation takes place on the left side of the aorta. The right trunk goes immediately behind the aorta and superior vena cava, and follows a transverse course to the right lung; the left has an analogous course on the left side of the body, but is much shorter than the right, on account of the latter passing behind the aorta and vena cava. Both are placed in front of the bronchi, and cross the course at first, being directed a little from below upwards; but they are subdivided exactly like the bronchi, and follow their course, being closely connected to them throughout: the artery is generally placed above its corresponding air-tube. For the organisation of this vessel, we refer to the article HEART.

The pulmonary veins, arising from the capillary system, follow a course analogous to that of the arterial divisions. These also accompany the air-tubes, and are situated under them. They unite gradually into larger and larger tubes, and form ultimately four considerable trunks, two belonging to each lung, and terminating in the left auricle of the heart. The superior right pulmonary vein passes out of the lung below the bronchus, and goes with a little obliquity downwards: the inferior ascends obliquely towards the auricle. The left veins have a similar arrangement; one descends, and the other ascends: they are more approximated than on

the right side. For the organisation of these vessels, see HEART.

The capillary vessels of the lung are distributed in infinite number through all parts of the organ, of the proper tissue of which they compose a very considerable share. As they have no connection with the nutrition of the part, and perform no secretion, they give passage only to the blood, and are hence remarkably distinguished from the general capillary system. These vessels cover in vast profusion the air-cells of the lungs; so that when they are injected with coloured fluids after death, the whole substance of the organ appears dyed of the peculiar colour. In them the blood is exposed to the air, and converted from the dark or venous into the red or arterial state.

The substance of the lungs, on superficial examination, offers a soft spongy mass, yielding easily to pressure, and restoring itself afterwards to its original state in an imperfect manner. When we view it more attentively, we observe on the surface small whitish lines circumscribing spaces of different figures, as triangular, quadrangular, &c. These are called lobules of the lungs, and vary considerably in size as well as figure. They are again divided into other smaller parts. These lobules are all connected together by a loose and soft cellular substance, which never contains any fat; and the same substance unites the reflected pleura to the external surface of the lung. If we tear the substance of the organ, and inflate it, the air fills the cells of this cellular texture, and makes it more sensible: it is also in some cases rendered more obvious, by being the seat of a watery deposition, which constitutes anasarca of the lungs. Its cells have no communication with the air vesicles, unless the latter be broken by inflation, as when we squeeze the air in them forcibly, they crack, and the air escapes into the cellular texture, uniting the lobuli. On the other hand, we might inflate the cellular substance distinctly from the air-cells.

Each lobulus of the lung consists of a branch of the air-tube with a corresponding proportion of cells, a branch of the pulmonary artery and vein, a portion of the pulmonary capillaries of the bronchial vessels and nervous ramifications, connected by the cellular substance already described.

The lymphatics of the lungs are numerous, and divided into a superficial and deep-seated set: the former constitute a net-work on the surface of the lung, and communicate also with the latter. They pass through numerous glands, called bronchial, placed on the trunks of the air-tubes and blood-vessels, partly within, but chiefly without the substance of the lung. Other larger glands are situated about the division of the trachea, and the absorbents of the right and left lung communicate in them. Some absorbents of the right lung terminate in the right absorbent trunk; the rest, with those of the left, end in the thoracic duct, passing through glands on the spine.

The bronchial glands are large in size, and numerous in proportion to the lung; but they vary in both these respects in different subjects. Several of the smallest are found on the bronchi, within the substance of the lung. Their colour is the most remarkable of their properties: in the adult it is a deep livid or black. Their consistence is rather soft, and a coloured fluid may be expressed from them, when cut or divided. It is now clearly ascertained that these bodies belong to the lymphatic system. Anatomists formerly conceived that they secreted a particular fluid, and poured it into the bronchi. We are quite ignorant of the cause of their peculiar black colour.

The lung, then, is made up of the tissues just described, covered on the surface by the very thin and transparent pleura pulmonalis, which is connected to the organ by

cellular substance, and gives it the smooth external surface.

Development of the Lungs.—The fetus has no respiration: from the circumstances under which it is placed in the uterus, it must obviously be altogether precluded from exercising that function; but it begins immediately after birth: hence the lungs, formed nearly as soon as the principal organ of circulation, possess, at a very early period, a considerable development and well-marked form. Their organisation, too, is perfect, or at least they are capable of executing their functions, before the time at which they naturally come into action: for there are instances of children born long before the end of the ninth month, as, for instance, at the seventh, or even sooner, who have been preserved alive by great care. In the early periods their colour is reddish; they then assume a slightly tawny hue, which is continued till the time of birth, and is not even changed by respiration, although the admission of air into the organs at that time is followed by the entrance of a larger quantity of blood.

The lobuli are very distinct in the fetus, and easily separable: the connecting substance appears to be more copious. Although the lungs are small in a fetus at full time, compared to those of a child who has breathed, we cannot say, as some anatomists represent, that they are extremely diminutive, and confined to the back of the chest. As they are at this time entirely free from air, they possess a density, which makes them sink instantly in water, when plunged into it either entire or in slices. They are penetrated by much less blood than after breathing has begun, and therefore reduced almost entirely to their solid and organised contents: they form at this time about $\frac{1}{4}$ th of the weight of the whole body.

As the function of respiration, which commences at the moment of birth, goes on afterwards uninterruptedly, and as the phenomena are as regular and perfect at this time as in more advanced age, we have no reason to expect that the intimate structure of the organ, that is, the arrangement of the different component tissues, will be different at that age from what we know of it in the adult: but the vascular trunks belonging to these parts exhibit some peculiarities, of which the details will be found in the articles HEART and CIRCULATION.

Breathing begins immediately after birth; the enlargement of the chest occasions the lungs to be distended with air, and consequently to become specifically lighter; a greater quantity of blood passes through them, and thus they acquire greater absolute weight. The increase of volume must be limited by the capability of enlargement in the chest; and this cannot be very considerable immediately on birth. This enlarged size is not, therefore, sufficiently marked, to be relied on as a proof that respiration has begun. It is a well-known fact, which we have already stated, that the lungs of an individual, who has breathed, swim in water, whether they be immersed entire or in slices. This is a property remarkably contrasted with what takes place under the same treatment before birth. A criterion has been sought for in this source, to determine, in doubtful cases, whether a child has been born dead or alive; and the consideration is a highly important one, from the influence it may produce on medical opinions, in cases of suspected child-murder. We shall only observe here, that the convulsive attempts to establish respiration, although not successful, may introduce air enough into the lungs to make them buoyant in water; that attempts to inflate them, in order to preserve the child, or after it has died, may have the same effect; that the disengagement of air by putrefac-

tion

tion may thus make them specifically lighter than water; not to mention, that the child may have breathed and died afterwards: so that the mere naked circumstance of the lung swimming is altogether an insufficient proof that the child has been murdered; and to condemn a mother to death on such grounds, exhibits a degree of ignorance and barbarity worthy only of the dark ages.

The increase of absolute bulk in the lungs after birth is a phenomenon very worthy of being remarked. We have stated already, that these organs in the fœtus, at full time, are $\frac{1}{10}$ th of the body. According to the researches of some German and French anatomists, they are no more than $\frac{1}{10}$ th, or $\frac{1}{12}$ th in a child who has breathed. There may be some variation in this point, but the organs are never so light as to approach at all to the proportion which they exhibit before birth; a fact which is highly important in its application to questions of supposed infanticide.

The colour of the lungs does not remain through life the same as at the time of birth. In the earlier years it has still the reddish, mixed with a tint of yellow, which we have already mentioned. After the twentieth year the livid or black spots appear, and become more numerous as age advances.

Physiology of the Lungs.—Two very different kinds of phenomena take place in the lungs. The first are entirely mechanical, and relate to the motions of the sides of the chest, by which the cavity is enlarged or diminished; and to the dilatation or contraction of the air-cells, and the admission and expulsion of the air, which are consequent on these motions. These have been already considered in those parts of the present article which relate to the motions of the thorax. The phenomena of the second kind are purely chemical, and consist of the various alterations which the respired air undergoes, of the changes effected in the composition of the blood, &c. For an account of these, the reader is referred to RESPIRATION, and HEAT, *Animal*.

These two divisions of the respiratory phenomena belong respectively to the two great classes of vital processes; the animal and organic. The motions of the chest are performed by voluntary muscles, and consequently are subject to the influence of the brain: hence a section of the medulla spinalis above the origin of the phrenic nerve, or a division of the nerves which supply the muscles of respiration, immediately annihilates these motions. Commonly, indeed, the motions of the chest are performed spontaneously, that is, without any exertion of the will; and they go on during sleep, when the action of all voluntary organs is suspended. But an act of the will can accelerate, retard, or otherwise modify the movements of the chest; and many of the muscles concerned assist in moving the trunk, on occasions that have nothing to do with respiration. The changes of the blood, on the other hand, go on in the capillaries, and are performed without our consciousness: the brain has no influence on them. The respiratory functions, then, offer the point of union of the animal and organic lives, in which these may reciprocally influence each other.

The chemical and mechanical phenomena of respiration are in a state of mutual dependence: the interruption of one is always quickly followed by the cessation of the other. Without the former, the latter would have no materials to act upon. If the mechanical phenomena were interrupted, the blood would no longer be fit to excite the brain; and that organ could not influence, in the proper manner, the intercostal muscles of the diaphragm: hence these muscles would become inactive, and even the mechanical phenomena must cease.

The heart does not influence these two kinds of phenomena in the same way.

The heart of black blood has obviously no power over the mechanical phenomena of the lungs; but it is essentially concerned in producing the chemical phenomena, as it sends to the organ the fluid which derives certain properties from the air, and imparts others to it. Thus, when the functions of the auricle or ventricle of black blood, or of the great venous trunks, are interrupted, as by a wound, or a ligature applied in experiments, the chemical phenomena are at once annihilated; but the dilatation and contraction of the chest still goes on. No blood arrives at the left ventricle, and consequently the requisite motion cannot be imparted to the brain: hence its functions are suspended, and consequently the intercostal muscles and diaphragm cease to act.

In the case of a wound affecting the auricle or ventricle of red blood, the aorta, or its great branches, when a ligature is artificially applied to the latter, or an aneurism bursts, &c. the functions of the lungs cease in the following order: 1. No more impulse communicated to the brain; 2. No more motion of that organ; 3. No more action exerted on the muscles, and consequently no more contraction of the intercostals and diaphragm; 4. No more mechanical phenomena. Without the latter, the chemical phenomena cannot take place: in the foregoing case, they were stopped for want of blood; in this, they cease from the interruption in the supply of air.

The preceding observations are derived from the *Recherches Physiologiques* of Bichat. In the 6th, 7th, 8th, and 9th articles of the second part of that work, he has entered at length into the consideration of the influence of the lungs on the heart, the brain, and the organs of the body in general; of which subjects he has given more clear and connected views than any other physiologist. We shall, therefore, avail ourselves of his labours in this concluding division of the present article.

Influence of the Death of the Lung upon that of the Heart.—The cessation of action in the lungs may begin either in the mechanical or the chemical phenomena. A wound exposing them extensively on both sides of the chest, and producing their sudden collapse; a division of the spinal marrow suddenly paralyzing the intercostal muscles and diaphragm; are cases in which the death of the lungs begins in the mechanical phenomena. It commences in the chemical, in asphyxia from noxious gases, from strangulation, submersion, exposure in vacuo, &c.

The heart's action can be interrupted by the cessation of the mechanical phenomena of the lungs only in two ways: 1. Directly, if the blood meets in the lungs with a real mechanical obstacle to its circulation; 2. Indirectly, because where the mechanical action of the lungs ceases, they no longer receive air, which is necessary to their chemical phenomena, the cessation of which interrupts the action of the heart.

All physiologists have admitted that the pulmonary circulation is interrupted in the former of these two ways. They have conceived, that where the lung is not distended, its vessels are folded and compressed, and therefore transmit the blood with difficulty: and by this explanation, derived from hydraulic phenomena, they have accounted for the death which ensues, where expiration is too long continued.

Goodwyn proved that a sufficient quantity of air remained in the pulmonary vessels to allow mechanically the passage of the blood; and, consequently, that protracted expiration is not fatal in the way commonly supposed. (Con-
nection

section of Life with Respiration, &c.) An experiment, which any one may very easily perform in his own person, will prove that point very easily. Let him expire as fully as possible, and not inspire again: the pulse is not changed, and consequently the circulation through the lungs is not impeded. But the numerous and varied experiments of Bichat place the subject beyond all doubt. Exhant, says he, the lungs of an animal, by means of a syringe inserted in the trachea, and open the carotid artery. Here the circulation ought to be suddenly interrupted, according to the common supposition, since the pulmonary vessels are reduced from their ordinary degree of distention to the greatest possible collapse and folding: yet the blood continues for some time to be forcibly thrown out of the opened artery, and must consequently circulate through the lung in this state of extreme collapse. The same circumstance is observed when the lungs collapse, in consequence of the thorax being opened on both sides; even if, in addition to this collapse, we exhaust the air more effectually with a syringe.

The pulmonary circulation is continued, and even performed with facility, when collections of water, pus, or blood, exist in the chest, and diminish, in a very considerable degree, the air-cells of the lungs; and when, consequently, the angles and folds of the vessels, if they are found at all, must be very considerable. We may conclude, then, that the interruption of the mechanical phenomena of respiration does not stop the heart's action directly; but that it operates indirectly, by cutting off the supply of the material, which is necessary for the exercise of the chemical phenomena.

The death which succeeds to protracted inspiration has been ascribed to the mechanical distention of the pulmonary vessels by the air, which has been supposed to impede the circulation through them. But this explanation is as ill-founded as that which we have just considered. Distend the lungs of an animal by injecting a large quantity of air, and confine this by a stopcock fastened in the trachea; then open the carotid artery. The blood continues to flow for some time with its natural freedom.

Two opinions have been entertained concerning the manner in which the interruption of the chemical phenomena of the lungs produces a cessation of the heart's action. According to Goodwyn, the black blood does not stimulate the left ventricle; so that, in his manner of viewing asphyxia, death takes place, because that cavity sends nothing to the different organs. Its source, therefore, is exclusively in the heart. Bichat conceives, that when the chemical phenomena of the lungs are interrupted, there is a general affec-tion of all the organs: that the black blood carries to every part debility and death, so that the organs do not cease to act because they receive no blood, but because they receive no red blood. The effects of the contact of black blood on the organs of the body will be illustrated presently; we shall consider here the phenomena of its contact with the parietes of the heart.

Many circumstances shew that the black blood is capable of stimulating the left ventricle, so as to excite it to contraction. If this were not the case, death should commence in asphyxia with the cessation of the heart's action, and the annihilation of the functions of the brain should be secondary. But, kill an animal by stopping the trachea, by placing it in vacuo, by drowning, or immersion in noxious gases, &c. and you will constantly observe, that the animal life is first interrupted, that the sensations, motions, and voice are suspended, so that the animal is dead externally, while the heart still beats and the pulse is kept up for some time. The different organs, therefore, do not cease to act in asphyxia,

because the heart sends them no blood, but because it sends a kind of blood which is not suited to them.

Let the trachea of an animal be stopped and an artery opened, the blood issuing from the latter is at first red, then grows gradually darker, and at last is black venous blood. Nevertheless, it is still expelled for some time with considerable force. If the lungs be exhausted by a syringe, previous to closing the trachea, and an artery then opened, black blood comes from it immediately, without going through the shades mentioned before, and a tolerably strong jet is kept up for some time. If the black blood did not possess the power of exciting the left ventricle, its flow should be suddenly interrupted in this case, where it can undergo no change from the lung, and exists in the aorta in the same state as in the venæ cavae.

It is moreover stated by Bichat, that he has re-excited the contractions of the left ventricle, after they had ceased in various kinds of violent death, by injecting black blood through one of the pulmonary veins. It is obvious too, that when suspended respiration is restored by inflating the lungs, the left ventricle must first propel the black blood with which it is loaded, before the red blood can arrive at the lungs. The heart of red blood has, therefore, the power of impelling black blood into all the organs; and in this way we explain the peculiar colour of the different surfaces in asphyxia.

The mere contact of black blood has no more sensible action on the internal surface of the arteries than on that of the heart. If, when the trachea is closed, an artery of the foot be opened, the blood is propelled from it for some time with the natural force.

"From these considerations and experiments we may conclude," says Bichat, "that the black blood has the power of exciting the internal surface, and determining the action of the heart and arteries; and that if no other cause interfered with their functions the circulation might be continued, not, perhaps, with equal force, but at least in a very sensible manner. What then are the causes which interrupt the circulation in the heart of red blood and in the arteries, when the lung transmits to them only black blood? For when the latter has flowed for some time, the jet is gradually weakened, and at last entirely ceases: if the stopcock fixed in the trachea be now opened, it is again speedily restored. I believe that the black blood acts upon the heart as upon all other parts, as we shall see that it influences the brain, the voluntary muscles, the membranes, &c.; that is to say, by penetrating its tissue, by debilitating each individual fibre. I am well convinced, that if black blood could be circulated in the coronary vessels, while the red should pass as usual through the left auricle and ventricle, the circulation would be interrupted almost as quickly as in the preceding cases." We conclude then, in general terms, and without attempting to determine how this takes place, that the heart's action ceases when the chemical phenomena of the lungs are interrupted, because the black blood, which penetrates its muscular fibres, is not capable of keeping up their action.

In this view of the subject, the right ventricle will be as much affected as the left, since the black blood is distributed equally to the fibres of each. Yet the latter ceases to act first, and this is so constantly and well known a fact, that the right side of the heart has been called the *ultimus moriens*. This arises, as Haller has already clearly explained, from the circumstance of the right cavities being longer excited than the left. (See HEART, and CIRCULATION.) It does not prove that the left ventricle dies first in asphyxia. If that were the case, the left auricle and ventricle should be distended with blood after death, and this distention should

be propagated from them into the pulmonary veins and right side of the heart; that is to say, the congestion of blood should begin in the reservoir which first ceases to act, and it should be propagated from that into the others. The examination of animals, who have perished from asphyxia, shews us, on the contrary, that the cavities of red blood and the pulmonary veins contain but a small quantity of black blood in comparison with that which distends those of the opposite side; that the point at which the blood has stopped is principally in the lung, from which we are to trace its stagnation in the whole venous system; and that the arteries contain as much in proportion as the corresponding ventricle, so that death cannot be supposed to have begun in it rather than in any other part.

Bichat states afterwards, that he cannot entirely reject the notion of the less aptitude of the black blood to stimulate the left ventricle. When an artery is opened, a stopcock being fixed in the trachea and closed, the jet of blood is gradually weakened; open the stopcock, and the blood becomes again immediately red, and is thrown out more forcibly. This change is too sudden to admit of our accounting for it by the red blood penetrating the tissue of the heart. Yet it may happen from the powerful motions of inspiration and expiration which the animal makes as soon as air enters the chest. For if an artery be opened, and respiration thus hurried, the jet of blood will be manifestly increased. On the whole, therefore, even if it be allowed that red blood is a more powerful stimulus to the heart than black, the excess must be very trifling.

In connection with this subject, we may consider the explanation of the remarkably distended state, in which the pulmonary artery, the right cavities of the heart, and the venous system are found in instances where death commences in the chemical phenomena of the lungs, compared with the comparatively empty condition of the system of red blood. The phenomenon is so remarkable as to have attracted the attention of all who have opened the bodies of animals killed by asphyxia; it has been commonly explained by the folds of the pulmonary vessels, which we have already considered.

The lungs are found in two very different states, according to the manner in which life ends: when death is instantaneous, they are not loaded with blood; the auricle and ventricle of black blood, the pulmonary artery, and the general venous system, are not remarkably distended. On the contrary, when the chemical phenomena of respiration are slowly destroyed, when an animal has been kept as long as possible in the distress and anguish which attend interruption of the functions of the lungs, these organs are extremely loaded with blood, and distended to a volume very far exceeding that which they present in the other case. In whatever condition the lungs of an animal, which has perished by asphyxia, may be found, whether they be loaded or empty, and consequently whether death have been brought on slowly or suddenly, the vascular system of black blood is always full of this fluid, particularly about the heart; there is constantly a great difference in this respect between it and the vascular system of red blood, and consequently the principal obstacle to the circulation is in the lung.

Bichat explains this phenomenon from certain considerations connected with the blood, the lung, and the heart.

1. The black blood circulating in the arteries is incapable of furnishing to the organs of secretion, exhalation, and nutrition, the various materials necessary for the exercise of those functions; or if it conveys the materials, it cannot excite the organs. Hence, the venous system receives an unusually large quantity of blood, as all that portion, which

is ordinarily removed by the functions just mentioned, enters it; and the difficulty of the passage through the lungs is proportionally augmented. All observers have been struck by the great abundance of blood found in the vessels in these cases.

2. The lung is no longer excited by red blood: the bronchial vessels carry black blood to it, and hence its powers are enfeebled, as those of the heart are by the same fluid conveyed to it by the coronary arteries. Again, the pulmonary capillary system contains nothing but black blood. That the tonic powers, by which the circulation is carried on in those vessels, must be much depressed from this cause, cannot be doubted. Moreover, the habitual excitation of the mucous surfaces by the atmospheric air is interrupted; and this must assist in lowering the tonic powers.

3. The auricle and ventricle of black blood act more weakly, and are less capable of surmounting any resistance in the lung in consequence of their fibres being penetrated by black blood. They can no longer resist the blood brought by the *venæ cavæ*, and become distended by it.

These considerations seem to account satisfactorily for the distention of the system of black blood in asphyxia; we have next to explain why the system of red blood contains a quantity comparatively so small. As the obstacle exists in the lungs, a smaller quantity arrives at the left side of the heart. The natural strength of the left ventricle and the arteries exceeds that of the right and the veins; consequently the former can more easily overcome the resistance of the capillaries of the body in general, than the latter can that of the pulmonary capillaries. Again, there is only one cause of retardation in the general capillary circulation, *viz.* the contact of black blood with the organs; while there is added to this cause in the lungs, the absence of the habitual excitation produced by the atmospheric air. Thus, we find in the lungs more resistance to the blood brought by the veins, and less force to overcome that resistance; while in the body in general the obstacles at the junction of the arteries and veins are more feeble, and the force tending to overcome them is greater.

Although the general capillary system offers less resistance to the arteries, than the pulmonary capillaries do to the veins in asphyxia, yet there is a manifest obstruction even here; and it gives rise to two remarkable phenomena. Black blood is collected in the arteries in a much greater quantity than usual, although in a smaller proportion than in the veins; hence injection succeeds badly in such subjects. The accumulation of black blood in the extremities of the arteries gives a livid colour to all the surfaces of the body, and a bloated appearance to the various parts, as the face, tongue, lips, &c. These two phenomena indicate a congestion of black blood in the arterial extremities, as the analogous appearances of the lungs denote a difficulty of passage through the pulmonary capillaries, where indeed the congestion is much more manifest, because the system is concentrated within a small space, while the other is spread over the whole body.

Influence which the Death of the Lung produces on that of the Brain.—The black blood acts upon the brain as it does on the heart; that is, by penetrating its tissue, and depriving it of the excitation necessary for keeping up its action. What we have said concerning the heart is therefore equally applicable to this subject. The experiments of Bichat on this point have been very numerous and diversified. He first transfused through a tube the blood of the carotid of one dog into the carotid of another: this does not hurt the animal if a vein be opened to obviate plenitude of the vessels.

It proves that the contact of extraneous red blood does not injure the cerebral functions. He then opened the jugular vein and carotid artery of a dog, received the blood of the former in a syringe heated to the temperature of the body, and injected it into the latter. The animal was almost immediately agitated; the respiration was hurried, and the distressing kind of suffocation that belongs to asphyxia was produced. Soon all the symptoms of the latter state appeared; the animal life was entirely suspended; the heart still continued to beat, and the circulation went on for half an hour, at the end of which time the organic life also was extinct. This experiment was often repeated, and invariably with the same result: about six ounces of black blood were injected. If the point of the syringe was inserted into the vein, so as to draw up the blood without any possibility of its coming in contact with the air, the result was the same, except that death came on rather more slowly. Various other substances, such as ink, oil, wine, water coloured blue, urine, bile, mucous fluids, produced the same effects. That the fatal effects arise in these cases from the action of the black blood, &c. on the brain, and not on the internal surface of the arteries, is proved by injecting them into the crural artery; the injection is never mortal, although numbness and even paralysis generally follow. If blood be taken from the carotid artery of an animal who is suffering asphyxia, and injected into that of another, the same effects with those already mentioned are produced. Also, if the carotids of two dogs are united by a silver tube, so that the heart of the one sends its blood to the brain of the other, and a stopcock be placed in the trachea of the former, no bad effect is produced, so long as that remains open. Close the stopcock, and black blood will be sent instead of red. Now, the dog whose carotid receives this blood becomes confused and agitated, drops his head, and loses his senses; but these phenomena come on more slowly than when black blood taken from the venous system is injected into the artery. If the transfusion be stopped, the symptoms of asphyxia may go off, and the animal recover; but death invariably follows the injection of black blood with a syringe.

In summing up his experiments, Bichat concludes, that the nature of the principles contained in the black blood render it either incapable of exciting the action of the brain, or actually injurious to the organ; but he cannot decide whether its influence is exerted negatively or positively.

He proceeds to make some interesting observations on the nature and treatment of asphyxia. "We might conclude," says he, "from the above-mentioned facts, that the best mode of treating those who are suffering from asphyxia, would be to impel into the brain red blood, which is its natural stimulus. Two points of time should be distinguished in asphyxia; 1, that in which the central functions alone are suspended; 2, when the circulation as well as the movements of the chest have stopped; for, in this affection, the animal life is first suddenly extinguished, and the organic ceases after a certain interval. In the first of these periods, the transfusion of red blood towards the brain, from the carotid of another animal, gradually re-animates the powers of motion; the cerebral functions are partly restored, and the arrival of blood in the brain is often announced by sudden agitations of the head, eyes, &c.; but this improvement soon disappears, and the animal relapses for the cause continues, as for example, if the stopcock in the trachea remains shut. On the other hand, if the stopcock be opened in this first period, the arrival of fresh air in the lungs almost always gradually re-animates these organs. The blood assumes the red colour, and is sent in that state to the brain,

and life is restored without transfusion, which is completely ineffectual in the second period of asphyxia, that is, when the organic movements, particularly those of the heart, are suspended. The transfusion of red blood towards the brain does not, therefore, afford us any remedy in the case of asphyxia. Neither does it succeed after the injection of venous blood into the brain by means of a syringe, which is invariably fatal. Asphyxia produced by injecting blood taken from the vein into the brain is more prompt and certain, than that occasioned by the gradual change of the red into black blood, consequent on interrupted respiration; and the nature of the two cases is manifestly different."

The phenomena of asphyxia, as observed in the human subject, coincide very well with what is observed in experiments on animals. In all cases the brain is first affected, its functions are annihilated, and the animal life, particularly so far as regards the senses, ceases; the internal functions are subsequently arrested. When asphyxia is produced in an animal with an artery open, it is curious to observe how the affection of the brain coincides with the change of colour in the blood, while the energy of the heart is unabated. Most of those who have been exposed to asphyxia, and have escaped suffocation, have experienced only a general kind of benumbing or paralysis, the seat of which is manifestly in the brain; while all in whom the pulse and heart have ceased to beat, certainly die. Almost all who have recovered say, that they felt first more or less violent pain in the head, produced probably by the first contact of black blood with the brain. Bichat considers the common notions of the effects of charcoal vapours on the head, and the expressions concerning the heaviness, giddiness, &c. produced by them, as strong proof that the first influence is in fact exerted on the brain. He observes further, that many individuals who have recovered from asphyxia produced by this cause, exhibit, for a longer or shorter period, various affections of the intellectual functions and voluntary motions, as for instance confusion of ideas, and unsteady motions of the lower limbs; the same effects, in a smaller degree, which apoplexy produces more sensibly. Convulsive motions have sometimes taken place almost immediately after exposure to mephitic vapours; and a pain in the head has often lasted many days after the disappearance of the other symptoms.

From the foregoing considerations, Bichat deduces the following conclusions; 1st, that when the chemical phenomena of the lungs are interrupted, the black blood acts upon the brain as upon the heart, that is, by penetrating its tissue, and thereby depriving it of the excitation necessary to its action; 2dly, that its influence is much more promptly exerted on the former than on the latter of these two organs; 3dly, that the inequality of their influence determines the difference observed in the cessation of the two lives in asphyxia, where the animal always ceases before the organic. Hence we may infer, how unfounded the opinion is, that in those who are executed by the guillotine, the brain still continues to live some time, and that sensations of pleasure and pain may still be referred to it. The action of this organ is intimately connected to its double excitation; 1st, by the motion, and 2dly, by the nature of the blood which it receives. As this excitation is suddenly interrupted in that mode of death, all feeling is as suddenly suspended.

Influence of the Death of the Lung on that of the Organs of the Body in general.—Bichat commences his view of this subject by examining the changes of colour which the blood undergoes when the chemical phenomena of the lungs are interrupted. He found the best method of observing these changes to be by fixing a stopcock in the trachea of an

animal, by which the quantity and kind of air introduced into the lungs can be regulated, and placing a small tube with a stopcock in an artery, as the carotid or crural, which enabled him to ascertain how the blood was altered.

1. When the stopcock is closed immediately after an inspiration, the blood grows darker in thirty seconds; it has acquired a deep tint in a minute, and it possesses entirely the appearance of venous blood in a minute and a half, or two minutes.

2. The production of the black colour takes place more quickly by several seconds, if the stopcock be shut after expiration, particularly if it has been a complete one.

3. If the air be drawn out of the lungs by a syringe, the blood becomes immediately black: twenty or thirty seconds are sufficient for the change. No successive gradations of colour are observed.

4. If the lungs be extended by injecting air into them, and closing the stopcock, a longer time is necessary for changing the blood into the black state: three minutes will then be required.

These phenomena are observed in the passage of the animal from a state of asphyxia to death: a series of an opposite nature is seen when it is restored from asphyxia to life.

1. When the stopcock, after being closed for some minutes, is opened, the animal immediately performs six or seven great inspirations and expirations. A jet of red blood succeeds the black, which was flowing before: and the interval between the two is at most thirty seconds. There is no successive change of tint, but a certain and decided alteration.

2. If a small quantity only of air be admitted, the change of colour is less considerable.

3. If fresh air be injected, and the stopcock then closed, the blood becomes red, but less manifestly than when the air is admitted by voluntary respiration: in the latter case the animal first expels the air that had become spoiled.

4. If the air inclosed in the lung be drawn out by a syringe, and fresh air injected, the change of colour is effected more rapidly than in the preceding case.

5. When the lung is exposed by cutting through the ribs, the circulation is continued for a certain time. If it be alternately distended and emptied by means of a syringe, the red and black colours are still produced so long as the circulation is kept up.

From the rapidity with which the blood, in these experiments, is changed from black to red on opening the stopcock, we cannot help concluding that the principle which causes this alteration passes directly from the lung into the blood, through the membranous lining of the air-cells. The acceleration of the motions of the heart in animals undergoing asphyxia, as in the famous experiment of Hook, by injecting air into the trachea, must be referred to the red blood penetrating the fibres of the heart, and putting an end to the debility which the contact of black blood was producing. Yet this method will never re-produce the motions of the heart when they have been once annihilated by the contact of black blood. Bichat has often tried this without success. The heart, says he, cannot be re-animated by the action of the air, unless the blood, coloured by that fluid, could penetrate the organ. When the circulation is stopped, how can this take place?

Hydrogen and carbonic acid gases were employed in respiration by filling bladders with them, and fixing them to the tube in the trachea. The bladder is alternately distended and emptied as the animal expires and inspires. He is at

first tolerably quiet, but in about three minutes begins to be agitated; respiration becomes hurried and troubled, the blood flowing from an artery grows darker, and is black at the end of four or five minutes. There was very little difference in the time required for the change, or intensity of the colour, whichever of the two gases was employed.

The reason why the change of colour takes place more slowly when these bladders are adapted to the stopcock, than when the latter is closed, seems to be, that the air contained in the trachea and its branches is repeatedly thrown from the lung into the bladder, and *vice versa*; so that its whole respirable proportion is successively presented to the blood. This motion cannot take place in the latter case; so that as soon as the pure part of the air contained in the bronchial cells is exhausted, the blood is no longer converted into the red state, although the trachea and its large divisions still contain a considerable quantity of air capable of serving the purposes of respiration. It appears that the conversion of the blood goes on only at the extremities of the bronchial ramifications, and that the internal surface of the large air-vessels has no connection with this phenomenon.

We have already seen that the action of the heart continues for some time after the chemical phenomena of the lungs have been interrupted; the arterial circulation is therefore still maintained, although the arteries contain a different fluid from that which is natural to them; and the organs of the body, accustomed only to the red blood, become penetrated, in consequence of this circulation, by black blood. Bichat has proved this by exposing various parts in an animal, while the stopcock in its trachea was closed, and the animal was consequently undergoing asphyxia. He has examined in this way the muscles, the nerves, the skin, mucous and serous membranes, and the granulations of wounds, and found that the black blood penetrated them all, and produced more or less conspicuous alterations in their colour, which was rendered either brown or livid. The phenomenon is very obvious in the skin, which always presents more or less extensive livid spots in asphyxia. These can only be explained by the existence of an obstacle to the transmission of the blood in the general capillary system: in the same way we account for the swelling of various parts, as the cheeks, lips, and head in general.

The black blood does not penetrate at all into some parts of the general capillary system, and the natural colour is consequently preserved: in others it manifestly enters and is obstructed, producing a dark colour at the part, and moreover a tumefaction, if it enters in large quantity: or, lastly, it may pass this system and enter the veins. In the two former cases the general circulation is arrested in the capillary system; in the latter, which is the more general, the course of the blood is suspended in the capillaries of the lungs.

The fact that the black blood continues to be circulated for some time after the chemical phenomena of the lungs have been interrupted, explains a phenomenon, which must have been observed by all who are much employed in dissections; *viz.* that in the dead body we meet with black blood only, even in the vessels which naturally carry red blood. However death may be produced, the functions of the lungs are troubled in the last moments of existence, and end before those of the heart. The blood still moves, although it no longer receives the influence of the air: it is therefore circulated black for a certain length of time, and remains in that state in the organs, although the circulation is much less evident than in asphyxia.

After having shewn that the interruption of the chemical phenomena of respiration prevents the black blood from being

being converted into the red state, and that this black blood is circulated through the body by the still surviving action of the heart, Bichat proceeds to shew that the black blood is not capable of maintaining the vital powers and activity of the organs, which are therefore killed by its contact. The red blood, he says, gives to the organs their natural and healthy excitation, by which their vital powers are supported. Possibly this effect may be produced by the combination of the different principles that colour it, with the various organs in which it is contained.

The organs of the animal and of the organic life have their actions terminated in different ways. The former, being entirely dependent on the brain, have their functions suspended as soon as those of the brain cease. We have already shewn that the contact of black blood produces the latter effect almost instantly; consequently the organs of sensation, locomotion, and the voice, must be suddenly paralysed in asphyxia. But the circulation of the black blood produces still further effects: when it penetrates the nerves, it renders them incapable of keeping up the communication between the brain and the senses on one side, and the locomotive and vocal organs on the other. The contact of the black blood with the organs themselves also annihilates their action. Inject into the crural artery of an animal blood drawn from one of its veins; the motions are soon weakened very perceptibly, and sometimes a momentary paralysis is produced. The effect cannot be ascribed to tying the artery, for that alone is often attended with no such consequence, whereas the result of injecting black blood is always the same, except indeed that it varies in duration and intensity. Sensation is also manifestly suspended in this experiment, but later than the power of motion. The effect is always produced, particularly if the injection of black blood be repeated three or four times at small intervals.

The organs of the internal life being independent of the cerebral action, have not their functions arrested, like those of the external life, by the suspension of that action. It is the contact of the black blood only that acts in this case, and consequently the death of these organs has one cause less than that of the locomotive and vocal parts, &c. We have already explained the influence of the black blood on the organs of circulation, and have shewn how the heart ceases to act as soon as it is thoroughly penetrated by that fluid. Its circulation in the vessels of the coats of the arteries and veins weakens those tubes, and suspends their action. It must be exceedingly difficult, if not impossible, to bring forward any strict proof that the secretions, exhalation, and nutrition cannot derive from the black blood materials suited to their offices; for that blood does not circulate in the arteries long enough to admit of our making experiments on those functions. We must rely, therefore, chiefly on the analogy of what happens in other parts, to prove that the organs of secretion, exhalation, and nutrition have their functions interrupted when black blood is sent to them. This statement is very much corroborated by the quantity of blood found in the vessels of those who have perished by asphyxia; it is so large as to be very troublesome in dissecting such bodies, which might naturally be expected when the usual outlets of the secretions, &c. are stopped.

From the preceding considerations Bichat concludes, that when the chemical functions of the lungs are interrupted, all the organs of the body cease to act simultaneously, in consequence of the contact of black blood; that their death coincides with that of the heart and brain, although it is not derived immediately from that cause; that, if it were possible for these two organs to receive red blood, while black was sent to the others, the functions of the latter would cease,

while those of the former would be continued: in a word, that asphyxia is a general phenomenon, taking place at the same time in all the organs, and not more decidedly marked in any particular one.

By resumming and comparing what has been said concerning the influence of the lungs on the heart, the brain, and the organs in general, we shall easily form an idea how all the functions successively terminate, when the respiratory phenomena are interrupted. When the mechanical phenomena are suspended; 1, there are no more chemical phenomena, for want of air to support them; 2, no more action of the brain, for want of red blood to excite it; 3, cessation of the animal life, that is, of the sensations, locomotion, and the voice, because the organs are no longer excited by the brain, nor by red blood; 4, cessation of the general circulation; 5, cessation of the capillary circulation, of secretion, absorption, and exhalation, in consequence of the organs of those functions being no longer excited by red blood; 6, no more digestion, for want of secretion and excitation of the digestive organs, &c.

When the chemical functions of the lungs are interrupted, the phenomena of death succeed in a different order: 1, interruption of the chemical phenomena; 2, suspension of the action of the brain; 3, cessation of the sensations, and of voluntary motions, consequently of the voice, and the mechanical phenomena of respiration; 4, stoppage of the heart's action, and of the general circulation; 5, termination of the capillary circulation, of the secretions, exhalation, absorption, and consequently of digestion; 6, annihilation of animal heat, which is the result of all the functions, and which does not leave the body until every kind of vital process is extinguished. In whatever function death may begin, it always ends in this.

There is a very intimate connection between the brain and the lungs: as soon as the former ceases to act, the functions of the latter are interrupted. This phenomenon, which is constantly observed in warm-blooded animals, can happen only in two ways: 1, because the action of the brain is directly necessary to that of the lung; or 2, because the latter receives from the former an indirect influence through the intercostal muscles and diaphragm, an influence which ceases as soon as the brain becomes inactive.

The lung can influence the brain directly only through the par vagum and the great sympathetic nerve. Irritation of the former renders respiration hurried, but this is an effect produced by any considerable pain. Division of one nerve of the eighth pair affects the breathing for a time: but this goes off, and the respiratory functions are then carried on with their accustomed regularity. If both nerves are cut, respiration is still more hurried: it does not return to its ordinary rate, as in the preceding experiment, but continues laborious for four or five days, when the animal perishes. Hence we see that the eighth pair is necessary to the pulmonary functions, and consequently that the brain has some influence on these functions: but the agency is not a very active or important one, since the functions of the lung are continued for a long time without it, and consequently respiration is not suddenly stopped, through its interruption in injuries of the brain. Experiments shew that the interception of the influence derived from the great sympathetic is equally inadequate to interrupt the functions of the lungs.

Since the lung is not affected immediately from the interruption of the action of the brain, there must be some intermediate organs, through which the former is acted on by the latter. These are the muscles of respiration. Subject, by the nerves which they receive, to the immediate influence of the brain, they become paralytic as soon as the action of

the

the latter has ceased. If the spinal marrow be divided between the last cervical and first dorsal vertebra, the intercostal muscles are paralysed, and respiration is carried on by the diaphragm only. If the phrenic nerves be cut, the diaphragm is rendered motionless, and the intercostals alone perform breathing. In either of these cases life may be continued for some time. But if the phrenic nerves and the spinal marrow about the bottom of the neck be both divided; or, which comes to the same thing, if the spinal marrow be cut through above the origin of the phrenic nerves, all communication between the brain and the agents of respiration is suspended, and death immediately follows. The difference of half an inch in the height at which the section is made is so important, that, if it be done at one point, the animal shall live fifteen or twenty hours, if half an inch nearer to the brain, he will die immediately. In the former case it is below, in the latter above the origin of the phrenic nerve: in the one instance respiration and consequently life ceases, because the diaphragm and intercostal muscles can act no longer; in the other the diaphragm carries on the respiratory functions, and consequently supports life for some time.

The facts just detailed shew, that when the nervous system is injured above the origin of the phrenic nerves, the phenomena of death succeed in the following order: 1, suspension of the action of the voluntary nerves below the injury, and consequently of the intercostal and phrenic; 2, paralysis of all the muscles of the animal life supplied by those nerves, particularly of the diaphragm and intercostal muscles; 3, cessation of the mechanical phenomena of respiration, for want of the agents necessary to those phenomena; 4, annihilation of the chemical phenomena. The interruption of all these motions is as rapid as their succession is quick in the natural order. Death comes on in this way from a division or compression of the medulla spinalis near the brain, from a luxation of the second vertebra, from concussion or compression of the brain, &c.

Thus we see that respiration is a function of a mixed kind, placed in a manner between the two lives, and serving as their point of contact, belonging to the animal life by its mechanical, and to the organic by its chemical phenomena. Hence the activity of the lung depends as much on that of the brain, which is the centre of the former, as on that of the heart, which is the central organ of the latter.

LUNGS, *Consumption of*. See CONSUMPTION.

LUNGS, *Dropsy of*. See DROPSY.

LUNGS, *Inflammation of*. See PERIPNEUMONY.

LUNGS, *Polypus of the*. See POLYPUS.

LUNGS, *Wounds of the*. See WOUNDS.

LUNGS *of Insects*. See ENTOMOLOGY and INSECTS.

LUNGS, *Sea*, in Zoology. See MEDUSA.

LUNGS, *Ship's*. See VENTILATOR.

LUNGSARP, in Geography, a town of Sweden, in West Gothland; 57 miles from Gotheborg.

LUNGSUND, a town of Sweden, in Warmeland; 25 miles N.E. of Carlstadt. N. lat. $58^{\circ} 48'$. E. long. $13^{\circ} 54'$.

LUNGU, a small island in the East Indian sea, near the coast of Queda. N. lat. $6^{\circ} 39'$. E. long. $99^{\circ} 42'$.

LUNG-WORT, in Botany, &c. See PULMONARIA.

LUNG-WORT, *Cow's* or *Bullock's*. See VERBASCUM.

LUNISOLAR, in Astronomy and Chronology, denotes something composed of the revolution of the sun, and of that of the moon.

LUNISOLAR Year, is a period of years made by multiplying the cycle of the moon, which is nineteen, by that of the sun, which is twenty-eight; the product of which is

five hundred and thirty-two; in which space of time those two luminaries return to the same points.

LUNKA, in Geography, a town of Samogitia; 40 miles N.E. of Miedniki.

LUNTENBURG, or BRZEDSLAW, a town of Moravia, in the circle of Brunn; 36 miles S.E. of Brunn.

LUNTZ, a town of Austria; 15 miles S.E. of Bavarian Waidhofen.

LUNULA, in Geometry. See LUNE.

LUNULA, the Half-moon, among the Romans, an ornament the patricians wore on their shoes.

LUNULA was also an ornament in form of a moon, worn by the ladies.

LUNULAR ANGLES. See ANGLE.

LUNULARIA, in Botany, so called from the crescent-shaped calyx, as it is now thought to be, of the male flowers. Mich. Gen. 4. t. 4. See *Marchantia cruciata* of Linnæus, who by mistake cites it by the name of *Lunaria*.

LUNULATUM FOLIUM. See LEAF.

LUOPIOIS, in Geography, a town of Sweden, in the province of Tavastland; 23 miles N. of Tavasthus.

LUPANNA, an island in the Adriatic, near the republic of Ragusa, which has a good and safe harbour. The soil, though stony, is by the industry of the inhabitants rendered fertile. The coasts abound with fish.

LUPARA, a town of Naples, in the Molise; 17 miles N.E. of Molise.

LUPATA, a chain of African mountains in Mocaranga. S. lat. 13° to 17° .

LUPERCALIA, feasts celebrated in Greece, and at Rome, in honour of the god Pan.

The word comes from *Lupercal*, the name of a place under the Palatine mountain, where the sacrifices were performed.

The Lupercalia were celebrated on the fifteenth of the calends of March, that is, on the fifteenth of February; or, as Ovid observes, on the third day after the ides. They are supposed to have been established by Evander, or brought by him from Arcadia into Italy. The Arundel Marbles ascribe the institution of these feasts to Lycaon, king of Arcadia, who afterwards polluted them by sacrificing human victims. This feast, after having been interrupted for some ages, was re-established in Athens, in the time of Pandira, as we learn from the 10th era of the same marbles. Lycurgus abolished at Lacedæmonia the barbarous custom of offering human victims. Valerius Maximus is of opinion, that this festival was only introduced in the time of Romulus, at the persuasion of the shepherd Faustulus.

On the morning of the feast, the Luperci, or priests of Pan, ran naked through the streets of Rome, striking the married women they met on the hands and belly with a thong, or strap, of goat's leather; which was held an omen promising them fecundity and happy deliveries.

The reason of this indecent custom, in celebrating the Lupercalia, took its rise, as it has been said, from Romulus and Remus: for while they were assisting at this feast, a body of robbers, taking hold of the occasion, plundered them of their flocks. Upon this the two brothers, and all the youth that were with them, throwing off their clothes, to be the more expedite, pursued the thieves and recovered their prey. This succeeded so well, that henceforward this ceremony became a part of the Lupercalia.

This feast was abolished in the time of Augustus; but it was afterwards restored, and continued to the time of the emperor Anastasius. Baronius says it was abolished by pope Gelasius, in 469.

LUPERCI,

LUPERCI, a name given to the priests of the god Pan.

The Luperci were the most ancient order of priests in Rome; they were divided into two colleges, or companies; the one called *Fabii*, and the other *Quintilii*: to these Cæsar added a third, which he called *Julii*.

Suetonius mentions the institution of this new college of Luperci as a thing that rendered Cæsar more odious than he was: however, it appears from the same passage of Suetonius, that this new company was not instituted by Cæsar, nor in honour of Pan, but by some friends of Cæsar, and in honour of himself.

LUPI CREPITUS. See **CREPITUS**.

LUPI, DIDIER, in *Biography*, a good harmonist. In the sixteenth century he set to music the spiritual songs of Guillaume Guerret, published in 1548. He is mentioned by Rabelais in the prologue of his fourth book.

LUPIA (from *λπιω*, to mangle,) denotes, in *Surgery*, a tumour of the ganglion kind, or, according to Cullen, a wen.

LUPIÆ, in *Ancient Geography*, a town and colony of Italy, in Messapia, supposed to have been near the site of the modern Lecce; 24 miles S.E. of Brundisium; but in that vicinity no vestige of antiquity remains.

LUPINASTER, in *Botany*, Bastard Lupine; a name given by Buxbaum and Ammann to a Siberian species of Trefoil, *Trifolium Lupinaster* of Linnæus.

LUPINE, the common name of a species of wild pea, cultivated principally for being turned in as a manure.

This plant requires but little trouble or labour in its cultivation, as it will thrive in any soil, except the bad chalky, and such as are very wet. It will even grow well upon poor, hungry, worn-out land, especially if it be dry and sandy. When sown in February or March, after a single very shallow ploughing, and slightly harrowed in, it will blossom two or three times between May and August, and prove an excellent enricher of the ground when ploughed in, just after its second blooming. The best time for mowing this sort of crop, is after a shower of rain, as the seeds drop easily out of the pods when they are gathered too dry. They must, however, be laid up very dry, or worms soon breed in them. They are inferior to many other plants for the above use.

LUPINUS, in *Botany*, so called by Pliny and other ancient writers. Professor Martyn says that the word owes its origin to *lupus*, a wolf, because plants of this genus ravage the ground, by over-running it, after the manner of that animal. *Lupinus* is also said to be derived from *λυπε*, grief, whence Virgil's epithet, *tristes lupini*, from the fanciful idea of its acrid juices when tasted producing a sorrowful appearance in the countenance. Both these ideas are avowedly taken from Vossius.—Lupine.—Linn. Gen. 371. Schreb. 492. Willd. Sp. Pl. v. 3. 1022 Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 28. Loureir. Cochinch. 429. Tournef. t. 213. Juss. 354. Lamarck Dict. v. 3. 620. Illustr. t. 616. Gærtn. t. 150.—Class and order, *Diadelphia Dican-dria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven. *Cor.* papilionaceous: standard heart-shaped, roundish, emarginate, its sides reflexed, compressed; wings nearly ovate, almost the length of the standard, not affixed to the keel, joined together in the lower part; keel cloven at the base, falcate in the upper part, pointed, undivided, of the same length but narrower than the wings. *Stam.* Filaments ten, all united, somewhat ascending, distinct above; anthers ten, five of them roundish, and as many oblong. *Pist.* Germen superior, awl-shaped, compressed, villous; style awl-shaped,

ascending; stigma terminal, obtuse. *Peric.* Legume large, oblong, leathery, compressed, acuminate, of one cell. *Seeds* numerous, roundish, compressed.

Ess. Ch. Calyx two-lipped. Five of the anthers round, five oblong. Legume leathery, torulose, compressed.

Obs. The calyx is subject to variations in different plants of this genus. Linnæus was acquainted with only seven species of Lupine, at least he has only described that number. Lamarck has seventeen in his dictionary; and Willdenow gives nineteen, which he arranges in three sections. *Se&.* 1. Herbaceous, with digitate or fingered leaves. *Se&.* 2. Shrubby, with similar leaves. *Se&.* 3. Herbaceous, with simple leaves.

Of the first section are

L. albus. White Lupine. Linn. Sp. Pl. 1015. (Lupini; Matth. in Diosc. v. 1. 392. *L. sativus*; Ger. em. 1217.)—Flowers alternate. Calyx without appendages; its upper lip emarginate, the lower undivided. A native of the Levant, cultivated in various parts of Italy and the south of Europe for food. The seeds are boiled; and afterwards steeped in water to extract their bitterness. It is common with the Romans to carry them in their pockets, eating them as they walk along in the streets. The flowers appear in July, the seeds in autumn.—*Stem* about two feet high, branched towards the top. *Leaves* fingered, composed of seven or eight narrow, oblong leaflets, hairy, of a darkish grey colour, covered with a silvery down. *Flowers* terminal, in loose spikes, white and sessile. *Legumes* straight, hairy, about three inches long, containing five or six seeds, which are roundish, flattened, extremely smooth and even, perfectly white, and unspotted.

L. luteus. Yellow Lupine. Linn. Sp. Pl. 1015. Curt. Mag. t. 140.—Flowers in whorls. Calyx with appendages; its upper lip cloven, the lower three-toothed.—A native of Sicily. It flowers in July and August.—*Stem* a foot high, branching. *Leaves* fringed, composed of seven, eight, or nine hairy leaflets. *Flowers* yellow, fragrant, in whorled spikes. *Legumes* ovate, flattish, hairy. *Seeds* ovate, a little compressed, yellowish-white, variegated with dark spots.—This is very commonly cultivated in flower-gardens, and should be sown in the spring with other annuals.

The second section consists of seven species, all natives of the Brazils or of Peru, and described originally by Lamarck only, from whom Willdenow has adopted them.

The third section comprises two fine species, *villosus* and *integrifolius*, of which we are not acquainted with any figure; the former is a native of Carolina, the latter of the Cape.—Loureiro describes two others of this section, *L. exchinchinensis* and *africanus*, but from the latter having its leaves ternate, like those of *L. trifolius*, Cavan. Ic. v. 8 t. 59, we are inclined to think it should be referred to some other genus.

LUPINUS, in *Gardening*, contains plants of the hardy, herbaceous, annual, and perennial showery kinds; of which the sorts mostly cultivated are, the white lupine (*L. albus*); the small blue lupine (*L. varius*); the narrow-leaved blue lupine (*L. angustifolius*); the great blue lupine (*L. hirsutus*); the yellow lupine (*L. luteus*); and the perennial lupine (*L. perennis*).

In the fourth sort there is a variety which has flesh-coloured flowers, and which is usually denominated the *royal* lupine.

Method of Culture.—These well-known flowering plants may be readily raised by sowing the seeds in patches in the borders, with other annuals in the spring, where they are to remain;

remain; thinning them afterwards where they are too close, and keeping them clean from weeds. In order to have a succession of flowers, the seed should be sown at different times, as in April, May, and June. The seed of those only which are first sown, however, ripens well. And in order to have good seed of the fourth kind, some seeds should be sown in a sunny border under a wall, or in pots placed under frames, the plants in the latter case being turned out and planted with balls of earth about them in the spring. The last sort should be sown at different times.

These are all useful plants for producing variety in the borders, clumps, and other parts of pleasure grounds and gardens.

LUPO, in *Geography*, a town of Hinder Pomerania, on a river of the same name; 15 miles E. of Stolpe.

LUPOGLAVO, a town of Iliria; 22 miles S.E. of Trieste.

LUPPURG, a town of Bavaria, in the principality of Neuburg; 16 miles N.W. of Ratibon.

LUPULUS, in *Botany*, the diminutive of *lupus*, a wolf, a name applied by the older botanists to the Hop, (see HUMULUS,) because, as the wolf preys upon other animals, so this plant, by immoderately impoverishing the soil in which it grows, starves its vegetable neighbours. Such at least is the explanation of Ambrosinus.

LUPUS, WOLF, in *Astronomy*, a southern constellation joined to the Centaur, whose stars in Ptolemy's Catalogue are nineteen; in the Britannic Catalogue, with Sharp's Appendix, twenty-four. See CENTAUR, and CONSTELLATION.

LUPUS SERVATUS, in *Biography*, a French abbot, celebrated for his learning, eloquence, and piety, descended from a considerable family in the diocese of Sens, was born about the commencement of the ninth century. He had from early youth a decided turn for theological pursuits, and in 828 he went to the abbey Fulda in Germany, where he studied the scriptures under the celebrated Rabanus, who, at his request, composed his "Commentaries upon the Epistles of St. Paul." He obtained considerable church preferment by the patronage of Lewis le Debonnaire, and Charles the Bald; and by the latter he was sent ambassador to pope Leo IV., and he was appointed, in conjunction with the celebrated Prudentius, to reform all the monasteries in France. The time of his death is unknown, but it is ascertained that he was living in 861. He was a considerable theological writer: and he published accounts of the lives of St. Wighbert, and of St. Maximin. A collection has been made of 130 of his "Letters" upon different subjects relating to difficulties in grammar, civil and ecclesiastical affairs, points of doctrine, discipline, and good morals, which are written with elegance, and throw much light on the history of the period in which he lived. Moreri.

LUPUS, CHRISTIAN, a learned Flemish monk of the order of St. Augustine, was born at Ypres in 1612, and embraced a religious life at the early age of fifteen. He completed his maturer studies at Cologne, and was afterwards sent to Louvain to teach philosophy; in which he acquired such celebrity, as to secure the particular esteem of the learned Fabio Chigi, then the papal nuncio in Germany, afterwards known as pope Alexander VII. In 1655, Lupus was one of the deputies sent to Rome by the university of Louvain, to negotiate some matters of importance with the papal court, which he executed to the satisfaction of his employers. On his return he was appointed professor of divinity at Louvain, the duties of

which he performed with great success. After this he filled the principal posts belonging to his order in that province. Pope Clement IX. would willingly have made him a bishop; and from Innocent XI. and the grand duke of Tuscany, he received repeated marks of esteem; the latter was desirous of settling upon him a considerable pension, that he might attach him to his court. He died in 1681, at the age of seventy. He left behind him many valuable works, of which the chief are "Commentaries on the History and on the Canons of Councils, both general and particular," in five volumes 4to.; "A Collection of Letters and Monuments, relating to the Councils of Ephesus and Chalcedon;" "A Collection of the Letters of St. Thomas of Canterbury, with a Life prefixed;" "A Commentary on the Rescriptions of Tertullian." Moreri.

LUPUS, in *Ornithology*, a name given by some authors to the *monedula*, or jackdaw, from his voracious appetite and habit of stealing. See CORVUS *Monedula*.

LUPUS, in *Surgery*, the disease frequently called *noli me tangere*.

LUPUS, in *Zoology*, a species of *Canis*. See WOLF.

LUPUS *Aureus*, the gold-coloured wolf, the name by which Latin authors call the creature known in English by the name of the jackal. See AUREUS.

LUPUS *Cervarius*, a name by which many authors have called the lynx, from its feeding on deer. See FELIS *Lynx*.

LUPUS *Marinus*, a name given by Jonston, Bellonius, and Gesner, to the *Canis hyæna*. See HYÆNA.

LUPUS *Marinus*, the Sea-wolf, the *Anarhichas lupus* of Linnaeus, in *Ichthyology*, a fierce and voracious sea-fish, confined to the northern seas of our globe. It is found in those of Greenland, Iceland, and Norway, on the coasts of Scotland and of Yorkshire, and in that part of the German ocean which washes the shores of Holland. Its head is larger in proportion to its size than that of the shark, and rounder, a little flattened on the top; the nose blunt; the nostrils very small; the eyes small, and placed near the end of the nose; the body is long, and a little compressed sideways; the back, sides, and fins, are all of a livid lead colour; the two first marked downwards with irregular, obscure, dusky lines, which in different fish have different appearances. The young are of a greenish cast; the belly is white; the skin is smooth and soft, but his teeth so remarkably hard and strong, that if he bites against an anchor of a ship, or other iron substance, he makes a loud noise, and leaves his marks in the iron; the fore-teeth are strong, conical, diverging a little from each other, stand far out of the jaws, and are commonly six above and six below, though sometimes there are only five in each jaw; these are supported withinside by a row of lesser teeth, which make the number in the upper jaw seventeen or eighteen, and in the lower eleven or twelve. The sides of the lower jaw are convex inwards, and the grinding teeth of this jaw are higher on the outer than the inner edges, and join to the canine teeth, but in the upper are separated from them; in the centre are two rows of flat strong teeth, fixed on an oblong basis upon the bones of the palate and nose; these and the other grinding teeth are often found fossil, and called *busonites*, or toad-stones. The two bones that form the under jaw are united before by a loose cartilage, serving by a free motion to the purpose of breaking, grinding, and comminuting its testaceous and crustaceous food, as crabs, lobsters, prawns, muscles, &c. At the entrance of the gullet, above and below, are two very small echinated bones. It has two fins, like wings, situated just under the gills; and one long dorsal fin running from the head to the tail,

tail, and another reaching from the anus to the tail; the tail is round at its end, and consists of thirteen rays. This fish grows to a large size, being sometimes found on the Yorkshire coast of the length of four feet, and near Shetland more than seven feet. Pennant.

LURA, in *Geography*, a town of South America, in the province of St. Martha, on the Madalena; 8 miles S. of Teneriffe.

LURBAH, a town of Bengal; 20 miles S.S.W. of Doefa. N. lat. $22^{\circ} 41'$. E. long. 85° .

LURCH, To, in *Fencing*, is to make an opening in order to invite your adversary to thrust at you, when you, being ready, may find a favourable reposte at him.

LURCHER, among *Sportsmen*, a kind of hunting dog, like a mongrel greyhound, with pricked ears, a shaggy coat, and generally of a yellowish-white colour. See DOG.

LURCY-LE-SAUVAGE, in *Geography*, a town of France, in the department of the Allier, and chief place of a canton, in the district of Moulins; 7 miles E.N.E. of Donjon. The place contains 2461, and the canton 8548 inhabitants, on a territory of 265 kilometres, in 12 communes.

LURE, in *Falconry*, a piece of red leather cut in form of a bird, with two wings fluck with feathers; and sometimes baited with a piece of flesh: wherewith to reclaim, or call back a hawk.

The word comes from the French *leurre*, which signifies the lure: formed, according to Skinner, from the Anglo-Saxon, *lura*, traitor; or, according to Tripaud, from *lora*, craftiness. See FALCON and HAWKING.

LURE, in *Geography*, a town of France, and principal place of a district, in the department of the Upper Saône, near the Ougnon. The place contains 1918, and the canton 12,339 inhabitants, on a territory of $227\frac{1}{2}$ kilometres, in 25 communes. N. lat. $47^{\circ} 41'$. E. long. $6^{\circ} 34'$.

LURGAN, a market and post-town of the county of Armagh, Ireland; it is in the north-eastern angle of the county, near Down, and consists of one long wide street, remarkable for cleanliness. Its trade consists in articles of the linen and muslin manufactures, of which the weekly sales are averaged from 2500*l.* to 3000*l.* Fine diapers for table linen manufactured in this town have been highly valued. Lurgan is 68 miles N. from Dublin.

LURGAN, a township of America, in Franklin county, Pennsylvania, containing 758 inhabitants.

LURGAN Green, a small post-town of the county of Louth, Ireland, pleasantly situated on Dundalk-bay. It is on the great northern road, 27 miles N. from Dublin.

LURIDÆ, in *Botany*, from *luridus*, pale, livid, or ghastly, alluding to the livid and blueish aspect, frequent in the tribe of plants thus denominated, which seems to announce their deadly effects on animal life. They constitute the 28th natural order, among the *Fragmenta* of Linnaeus, and are exemplified by *Digitalis*, *Nicotiana*, *Atropa*, *Hyoscyamus*, *Datura*, *Physalis*, *Capsicum*, *Solanum*, *Verbascum*, *Celisia*, *Lycium*, *Cestrum*; to which *Triguera* of Cavanilles, as well as *Witheringia* of P'Heritier, are properly added by Giseke. But *Browallia*, *Ellisia*, *Strychnos*, *Ignatia*, and above all *Catebau*, are with less reason referred hither by Linnaeus.

The true *luridæ* have commonly a fetid herbage, though sometimes a sweet-smelling flower. They act powerfully upon the nerves, in whatever manner they are taken inwardly, and prove, under careful management, in some cases, very valuable medicines, though naturally violent poisons.

LURIGANCHE, in *Geography*, a town of Peru, in the jurisdiction of Lima.

Vol. XXI.

LURIN, a town of Peru, in the jurisdiction of Lima.

LURKJAN, a town of Persia, in the province of Chulistan; 50 miles N. of Suster.

LURY, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges, situated on the Arnon; 13 miles W. of Bourges. The place contains 512, and the canton 4575 inhabitants, on a territory of 170 kilometres, in 9 communes.—Also, a town of the island of Corfica; 13 miles N. of Bastia.

LUS, *Str.*, a town of Mexico, in the province of Guatemala; 12 miles E. of Guatemala.

LUSATIA, a marquisate of Saxony, bounded on the N. by the Mark of Brandenburg, on the E. by Silesia, on the S. by Bohemia, and on the W. by Saxony; about 84 miles long, and 45 broad, divided into Upper and Lower Lusatia. The former abounds in mountains and hills, and enjoys a purer air than the latter, which is covered with a great number of woods. Peat and turf are found in different parts. Upper Lusatia is ill adapted to agriculture, but affords plenty of game. Lower Lusatia has heaths and fertile tracts. In both rye, wheat, barley, and oats are cultivated, together with buck wheat, peas, linets, beans, and millet. Flax is also cultivated. As to orchard and garden fruits, and the culture of hops, tobacco, and wine, Lower Lusatia is preferable to the Upper. Nevertheless, the products of the country are not adequate to its consumption, so that corn, fruit, hops, garden stuff, and wine, are imported into both these marquisates. Cattle are bred in considerable number, and the rivers, lakes, and ponds afford various sorts of good fish. In some parts are found pipemaker's clay, and stone quarries. Stones resembling the Bohemian diamonds, agates, and jaspers, and iron stone, are met with in several places; and here is a variety of medicinal springs. The chief rivers are the Spree, the Black Elster, and the Pulsnitz. In Upper Lusatia are reckoned six towns, called "The Six Towns," 16 smaller towns, and four market towns; and in the Lower four towns, which appear at the land diets, 13 county towns, and two market ones. The first known inhabitants of this country were the Semnones, or Senones, who were succeeded by the Wandalers, and these again in the 7th century by a Slavonian people, called the Sorber-Wends. In the 12th century the inhabitants of this country were intermixed by emigrants from the Low Countries and the Rhine. Some of the towns are now wholly peopled by Germans, but in the villages the Wends are more numerous than the Germans. Lutheranism was introduced into this country as early as the year 1521; it generally prevailed, and has been the permanent religion of the country. In 1750, the Hernhuters obtained protection as faithful subjects, and in consequence of purchasing several considerable estates, they have not only acquired civil power, but the patronage of churches. The inhabitants of Lusatia gain their subsistence by the manufacture of numerous woollen and linen stuffs; which mostly flourish in Upper Lusatia. The manufactures of Lusatia have been promoted by the emigration of the Protestants, who were driven thither from Bohemia and Silesia by the conduct of the emperors Ferdinand II. and III. and also of Leopold; and thus they have been extended, beyond cloth and linens of various sorts, to those of hats, leather, paper, gunpowder, iron, wax, glass, and wax-bleaching, and a variety of handicraft arts and operations. By these manufactures they have been enabled to carry on a trade, so that the commodities they dispose of exceed those which they import, which are wool, yarn, and silk, corn, fruit, hops, &c. The whole of Lusatia, except a small part which is subject to Prussia,

fia; belongs to Saxony, having been ceded to the elector about the middle of the 16th century, in consideration of a large sum of money advanced by the elector to the emperor, in his war with the Bohemians.

LUSCHETZ, a town of Bohemia, in the circle of Sclia; 8 miles S.W. of Prague.

LUSCINIA, in *Ornithol. gy.* a species of *Motacilla*, which see. See also NIGHTINGALE.—Also, a species of *Certhia*. See *CERTHIA Flavesc.*

LUSCINIOL A, the *Begonch* of Pennant, and *red warbler* of Latham. See *MOTACILLA Schoenob. aus.*

LUSCINIUS, OTTOMARUS, in *Biography*, a Benedictine monk, born at Stralsburg, but an inhabitant of Angsburg, published in 1536 a work, entitled “*Musurgia seu praxis Musicae*,” in small oblong quarto; a book chiefly curious and valuable for the representations of such musical instruments as were used in Germany at the time it was written, which, though coarsely cut in wood, are accurately drawn. There are, among keyed-instruments, the virginal, spinnet, and clavicord, all three in the form of a small modern pianoforte; an upright harpsichord; a regal or portable organ, chiefly composed of reed-stops, and in Roman Catholic countries used in processions; and a large or church-organ. Of bowed-instruments we have here only the monochord, rebec, or three-stringed violin, and the viol da gamba. The vielle, lute, harp, and dulcimer; cornet, schalmey, or base clarinet, both played with reeds; flutes of various size, among which is the *Storckflut*, flute traversiere, or, as we call it, the German flute; which accounts for its name, as we believe, at this early period, it was unknown to the rest of Europe. There are four other wind-instruments, peculiar to Germany and northern countries, exhibited here: as, first, the ruspflut, or Russian flute; second, the krumhorn, or crooked horn, a kind of shawm, in imitation of which we have a reed-stop in our old organs, called the cromhorn, which has by some been imagined to be a corruption of the word Cremona; third, gamsen horn, or wild goat’s horn; and, fourth, the zinke, or small cornet. After these we have the bag-pipe, trumpet, sacbut, fiddrum, kettle-drum, French-horn, bugle-horn, and even the Jews-harp, and clappers. Most of these instruments being in common use, and well known, need no representation after the rude types of them given by Luscinius, as they have been since much better delineated and engraved in Martenens, Kicher, and in still later musical writers.

LUSEPARA, in *Geography*, an island that lies in the south entrance of the straits of Banca. S. lat. 3° 10’ 30”. E. long. 116° 15’.

LUSHBURGH, or LUXENBURG, in our *Old Writers*, a base sort of foreign coin, made of the likeness of English money, and brought into England in the time of Edward III. to deceive the king and his people; on account of which it was made treason, for any one willingly to bring any such money into the realm, as knowing it to be false. Stat. 23 Edw. III. 3 E. R. 1.

LUSIAD of *Lancet*. See CAMOENS.

LUSIGNAN, in *Geography*, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Poitiers. The place contains 1290, and the canton 13,147 inhabitants, on a territory of 342½ kilometres, in 10 communes. N. lat. 46° 26’. E. long. 0° 14’.

LUSIGNY, a town of France, in the department of the Aube, and chief place of a canton, in the district of Troyes. The place contains 1155, and the canton 7225 inhabitants, on a territory of 180 kilometres, in 14 communes.

LUSITANIA, in *Ancient Geography*, one of the two provinces into which Hispania Ulterior was divided; the

other being Bætica. (See HISPANIA.) Its limits have been variously defined by different authors, and particularly by Pliny and Ptolemy. Strabo intimates, that this province extended from the Tagus to the Cantabrian ocean, or at least the Promontorium Celticum. That part of it, situated betwixt the Anas and the Tagus, was denominated Celtica, or the country of the Celts. After Augustus made the disposition of Spain, referred to under the article *Hispania*, the Anas bounded Lusitania on the south, and the Durus on the north; so that the whole tract lying betwixt the Durus and the Cantabrian ocean was annexed to the Provincia Tarraconensis. The interior limits of Lusitania, upon the frontiers of the Vettones and Carpetani, are differently fixed by different authors. The Lusitani possessed the district bordering upon the Atlantic ocean, and stretching itself from the mouth of the Anas to the Promontorium Sacrum, now known by the name of Cape St. Vincent. The situation of the Celtici, whose true name was Mirobrigenes, according to Pliny, may be inferred from the preceding part of this article. Some of the ancient geographers make the Turduli and the Turdetani one nation, particularly Ptolemy and Strabo; though they were considered in a different light by Polybius. However this be, the Turdetani were undoubtedly a powerful people, since they occupied a considerable part both of Lusitania and Bætica, as we learn from Strabo. The same may be said of the Vettones, who spread themselves over a large tract, terminated on the north by the Durus, and on the south by the Tagus. Nevertheless, as the ancients differ with regard to the extent of territory every one of those nations or cantons possessed, it is probable that their frontiers were not always the same. Some authors assert Vettonia, or the country of the Vettones, to have been a province distinct from Lusitania, and limited on the south by the Anas; and this notion is countenanced by an inscription in Gruter. The principal cities of this province are Barbarium Promontorium, Olisippo, Tagi Fluvii Ostia, Fortes Fluv., Lunæ Montis Promontorium, Mondæ Fluv. Ostia, Vaci Fluv. Ostia, Doræ Fluv. Ostia, Hannibal. Inland towns were Lavara, Arctium, Salium, Elbocoris, Araducta, Verarium, Velladis, Eminium, Chretina, Arabriga, Scabificus, Tacubis, Concordia, Talabriga, Langobriga, Mendeculia, Caaurum, Turmogum, Burdua, Colernum, Mallæcus, Amma, Ebura or Eboræ, Norba Cæsarea, Liciniana, Augusta Emerita, which was the capital, Evandria, Geræa, Cæcilia Gemittina, Capasa, Conimbria, Collipo, Bletisa, Salamanica, Salatia, Pax Julia, and some others of less note. The chief promontories of Lusitania were the Promontorium Sacrum, or Cape St. Vincent; P. Barbarium, or Cape Spichel; and the P. Magnum, or Olisiponense, denominated by some moderns Cape de Rocca Santa; to which some add a fourth, called by Pliny Cuncus or the Wedge, supposed to be now known by the name of Cape St. Mary. The principal ports of this province were those of Olisippo or Lisbon, and Hannibal. The only island on the coast of Lusitania was the Londobris of Ptolemy, the Bælinga or Bailinges of the moderns. The only mountain of note in this country was the Mons Herminius of Hirtius, or the modern Arrimmo, since known by the name of Sierra de Ebreita, running from north to south, between the provinces of Beira and Trallos Montes. On the top are two extensive and deep lakes, calm when the sea is so, and rough when that is stormy. These lakes are supposed to have some subterranean communication with the ocean. Herminius Minor is now Sierra de Marvão. The warlike inhabitants of the former were called Plambarii, from their lead-mines and works. The most celebrated rivers of Lusitania

ania were the Anas, now Guadiana, the Tagus or Tago, and the Durio or Douro; to which may be added the Munda or Mendago, and the Vacus or Voga: all these flow from east to west, and discharge themselves into the Atlantic ocean. This province produced a considerable quantity of gold, particles of it being mixed with the sand of the Tagus. The lead-mine of Medobriga or Meidobriga, at the foot of Herminius Minor, was famous.

The Lusitanians, according to Strabo, preferred exulting upon the plunder of their neighbours to the improvement of their own lands, though the soil was naturally fertile and rich. In other cases their manner of living was rude and simple. They used to warm themselves by means of fire-stones made red-hot. They bathed in cold water, eat only of one dish at a meal, and very sparingly. Their dress was commonly black. They made no use of coin, but either bartered one commodity for another, or for some plates of silver, flatted with the hammer, and cut into pieces. They used, like the Egyptians, Gauls, and other ancient nations, to expose their sick on the highways, that travellers might direct them to proper medicines for their cure. They were exceedingly robust, and so warlike that the Romans did not conquer them without great difficulty and length of time. See PORTUGAL.

LUSITANICA *Rubra Bolus*, is an impure earth, of a florid red colour, compact texture, and heavy: it colours the hands, and is very friable, readily dissoluble in water, and raises with it a strong ebullition; it melts readily in the mouth, has a strong astringent taste, is gritty, and adheres firmly to the tongue. It acquires hardness and a brighter colour by burning; it is of an alkaline quality; it is dug in the kingdoms of Portugal and Spain; it is also found near the Havannah and La Vera Cruz in New Spain. It has been esteemed a very valuable astringent, and an effectual remedy for fluxes and other distempers of that kind. It has been also accounted alexipharmic by the Spaniards and Portuguese. They make an earthen ware of this bole, which they call bucaros: the ware is of a fine red colour, smooth, and polished, though it is merely dried, and not glazed. They use it to filter, cleanse, and cool the water. Vessels of the same kind are also brought from the Havannah and Vera Cruz.

LUSK, in *Geography*, a fair-town in the county of Dublin, Ireland. According to Archdehl, an abbey was founded here in the first ages of Christianity; and there is adjoining the angle of the steeple of the church, one of those ancient round towers so peculiar to Ireland: it is in good preservation, and rises several feet above the battlements of the steeple. It is 11 miles N. by E. from Dublin.

LUSPA, a town of Sweden, in East Bothnia; 28 miles E. of Chri linefadt.

LUSSAC, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Libourne; 6 miles E.N.E. of Libourne. The place contains 2032, and the canton 9072 inhabitants, on a territory of 157½ kilometres, in 16 communes.—Also, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Montmorillon; 6 miles W. of Montmorillon. The place contains 1379, and the canton 9470 inhabitants, on a territory of 400 kilometres, in 13 communes.

LUSSAN, MARGARET DE, in *Biography*, was born at Paris in 1682. Her parents were in the lower rank of life; the mother being a fortune-teller, and the father a coachman. She, by some means, attracted the notice of the learned Huet, who, struck with the vivacity of her temper, encouraged her to write romances. She derived great ad-

vantage in the formation of her taste, from her conversations with la Serre de Langlade, to whom she was much attached: but the love was not mutual; her charms were wholly mental; her person and manner were even so; but she was generous, humane, and constant in her friendships. She died at the age of 75. Her works are, "L'Histoire de la Comtesse de Gournay," "Anecdotes de la Cour de Philippe Auguste," "Mémoires Secrets et Intrigues de la Cour de France sous Charles VIII.," "Mars d'Angleterre," "Annales de la Cour de Henri II.," "La Vie du brave Crillon."

LUSSAN, in *Geography*, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzès; nine miles N. of Uzès. The place contains 907, and the canton 5493 inhabitants, on a territory of 239 kilometres, in 13 communes.

LUSSEMEN, a town of Prussia, in the province of Ermeland; 18 miles E.S.E. of Heilberg.

LUST, at *Sea*. If a ship heel either to the star-board or port, the seamen say she hath a *lust* that way; and they say so though it be occasioned only by the shooting of her ballast, or by the unequal stowing of things in the hold: though it is more properly said of a ship, when she is inclined to heel any way upon account of her mould or make.

LUST-cort, in *Botany*. See *SUN-dew*.

LUSTER, or **LUSTRE**, gloss, or brightness appearing on any thing; particularly on manufactures of silk, wool, or stuff.

LUSTER is also used for a certain composition, or manner of giving that gloss or brilliance.

The lustre of silks, in which their chief beauty consists, is given them by washing in soap, then clear water, and dipping them in alum-water cold.

The lustre of black taffety is given by double-brewed beer, boiled with orange or lemon-juice; that of coloured taffetas with water of gourds, distilled in an alembic. Curriers give a lustre, or gloss to the leather several ways, according to the colour to be illustrated. For blacks, the first lustre is with juice of barberries; the second with gura arabic, ale, vinegar, and Flanders glue, boiled together: for coloured leathers they use the white of an egg beaten in water: moroccos have their lustre from juice of barberries, and lemon or orange.

For hats, the lustre is frequently given with common water; sometimes a little black dye is added. The same lustre serves skinners, except that in white furs they never use any black dye. For very black furs they sometimes prepare a lustre of galls, copperas, Roman alum, ox's marrow, and other ingredients.

The lustre is given to cloths and molairs, by pressing them under the calender.

LUSTER, an appellation given to a branched candlestick, when made of glass. See *BRANCH* and *JESSE*.

LUSTIG, JACOB WILHELM, in *Biography*, organist of St. Martin's church in Groningen, published, in 1771, in the Dutch language, "An Introduction to the Art of Music, 2d edition, corrected and enlarged," 8vo. This introduction is better digested, and more abundant in useful information, than the generality of elementary treatises. The author had read, meditated, and studied music regularly, both in theory and practice; and was a good composer of the old school. He had been a disciple both of Mattheson and Telemann. We have seen a book of lessons of his composition, which has great merit. In this book we found the cross-hand jig, in $\frac{3}{8}$, which the little Frederica, afterwards Mrs. Wynne, and other infant performers, used to play at the end of a minuet of Tartini with variations by Pa-

radies, generally known by the name of Paradies' minuet. In 1772 we had the pleasure of converſing with this worthy profeſſor (*Luſtig*), and of hearing him play on the organ of St. Martin's church in Groningen, of which he had been organiſt 44 years; ſtill retaining his hand, and, a few allowances made for change of taſte and ſtyle, he was ſtill a very able and good organiſt.

LUSTRAL, an epithet given by the ancients, to the water uſed in their ceremonies, to ſprinkle and purify the people. From hence the Romanists have borrowed the holy water uſed in their churches.

LUSTRAL day, *dies Luſtricus*, that whereon the luſtrations were performed for a child, and its name given; which was uſually the ninth day from the birth of a boy, and the eighth from that of a girl. Though others performed the ceremony on the laſt day of that week wherein the child was born, and others on the fifth day from its birth.

Over this laſt day the goddeſs Nundina was ſuppoſed to preſide; the midwives, nurſes, and domeſtics, handed the child backwards and forwards, around a fire burning on the altars of the gods, after which they ſprinkled it with water; hence this feaſt had the name of *Amphidromia*. The old women mixed ſhiva and duſt with the water. The whole ended with a ſumptuous entertainment. The parents received gifts from their friends on this occaſion. If this child was a male, their door was decked with an olive-garland; if a female with wool, denoting the work about which they were to be employed. P. ter.

LUSTRATION, **EXPIATION**, in *Antiquity*, ſacrifices or ceremonies, by which the Romans purified their cities, fields, armies, or people deſiled by any crime, or impurity. Some of the luſtrations were public, others private.

There were three ſpecies, or manners of performing luſtration; viz. by fire and ſulphur; by water; and by air; which laſt was done by fanning and agitating the air round the thing to be purified.

There was alſo a peculiar kind of luſtration for young children.

Lomier has a volume expreſs on the luſtrations of the ancients: *John Lomieri Zutphanenſis Epimenedes, ſive de veterum Gentium Luſtrationibus*; firſt printed at Utrecht in 1681, and ſince, with additions, in 1702, 4to.

All perſons, ſlaves only excepted, he ſhews, were miniſters of ſome ſort of luſtration. When any one died, the houſe was to be ſwept after a particular manner, by way of purification; the prieſt threw water on new married people, with the like intention. To purify themſelves, people would even ſometimes run naked through the ſtreets; ſuch was their extravagance. And, as if fancy was not fertile enough in inventing modes of luſtration, they even uſed enchantments to raiſe the dead, in order to get inſtructions what they muſt do to purge themſelves of their ſins. Add, that they frequently raiſed the opinion of the ſanctity of their expiations by fictitious miracles.

It was common, on theſe occaſions, to ſhed human blood: the prieſts of Cybele, Bellona, and Baal, made cruel incifions on themſelves. Erechtheus, king of Attica, ſacrificed his daughter to Proſerpina. Several had their throats cut at Rome, to obtain the emperor's health from the gods. Thoſe who commanded armies offered one of their ſoldiers to appeaſe the anger of the gods; that he alone might ſuffer all the wrath the army deſerved.

All ſorts of perfumes, and odoriferous herbs, had place in luſtration. The egg was much uſed among them, as being the ſymbol of the four elements; its ſhells, they ſay, repreſent the earth; the yolk, a globe of fire; the white, reſembles the water; and beſides it has a ſpirit, they ſay,

which repreſents the air. For this reaſon it is, that the bouzes, or Indian prieſts, believe to this day that the world came out of an egg. There is ſcarce any pot-herb, pulſe, tree, mineral, or metal, which they did not offer the gods by way of expiation: nor did they forget milk, bread, wine, or honey; what is more, they made uſe of the very ſpittle, and urine.

The poets had feigned, that the gods purified themſelves, and they did not omit to purify their ſtatues. They made luſtration for children the eighth day after their birth. When a man who had been faſely reputed dead, returned home, he was not to enter his houſe by the door. It was a ſettled cuſtom to offer no expiation for thoſe who were hanged by order of juſtice; or that were killed by thunder. Neither did they offer any for thoſe who were drowned in the ſea; it being the common opinion, that their ſouls perished with their bodies. And hence it was, that perſons in danger of ſhipwreck, ſometimes thruſt their ſwords through their bodies, that they might not die in the ſea; where they thought their ſoul, which they ſuppoſed to be a flame, would be totally extinguished. The moſt celebrated expiatory ſacrifice was the hecatomb, when they offered a hundred beaſts; though they commonly did not offer ſo many, but contented themſelves with killing twenty-five; but thoſe being quadrupeds, their feet came to an hundred.

The manner of the Macedonians purifying their army by luſtration was this; at the time of their feſtival *Xanthica*, they divided a bitch into two halves, one of which, together with the entrails, was placed upon the right hand, the other upon the left; between theſe the army marched in this order: after the arms of the Macedonian kings, came the firſt line of the army, conſiſting of horſe; theſe were followed by the king, and his children, after whom went the life guards; then followed the reſt of the army: this done, the army was divided into two parts, one of which being ſet in array againſt the other, there followed a ſhort encounter in imitation of a fight. Potter, *Archæol. Græc. lib. ii. c. 20. tom. i. p. 417.*

Luſtrations, and luſtratory ſacrifices, were not only performed for men, but alſo for temples, altars, theatres, trees, fountains, rivers, ſheep, fields, and villages. When the Arval brothers offered a victim for the fields, their ſacrifice was called *ambarvalia*.

Cities were alſo to be purified, from time to time: ſome made the victim walk round their walls, and then ſlew him. The Athenians ſacrificed two men, one for the men of their city, and the other for the women. The Corinthians ſacrificed the children of Medea ſo: though the poets ſay, Medea killed them herſelf. The Romans performed the ceremony of purifying their city every fifth year; whence the name of *luſtrum* was given to the ſpace of five years.

Divers of the expiations were auſtere: ſome faſted; others abſtained from all ſenſual pleaſures; ſome, as the prieſts of Cybele, caſtrated themſelves; others, that they might live chaſte, eat rue, or lay under the branches of a ſhrub called *agnus caſtus*.

They caſt into the river, or at leaſt out of the city, the animals or other things that had ſerved for a luſtration, or ſacrifice of atonement; and thought themſelves threatened with ſome great miſfortune, when by chance they trod upon them. At Marſeilles, they took care to feed a poor man for ſome time; after which, they charged him with all the ſins of the country, and drove him away: thoſe of Leucade faſtened a number of birds to a man charged with their ſins, and in that condition caſt him headlong from a high tower; and if the birds hindered his being killed, they drove him out of the country.

Some

Some of these ceremonies were abolished by the emperor Constantine, and his successors; the rest subsisted till the Gothic kings were masters of Rome, under whom they expired; except that several of them were adopted by the popes, and brought into the church, where they make a figure to this day: witness the numerous consecrations, benedictions, exorcisms, ablutions, sprinklings, processions, feasts, &c. still in use in the Roman church.

LUSTRINGS. A company was incorporated for making, dressing, and lustrating alamanodes and lustrings in England, who were to have the sole benefit thereof, by stat. 4 and 5 W. and M. And no foreign silks known by the name of lustrings or alamanodes are to be imported, but at the port of London, &c. Stat. 9 and 10 W. III. c. 43. See **SILK**.

LUSTRUM, a term used by the Romans, to signify a space of five years.

Varro derives the word from *lucro*, to pay; because at the beginning of every fifth year they paid the census, or tribute imposed by the censors; whose authority, at their first institution, was continued them for five years; though afterwards it was abridged to one. Others rather derive the word from *lustrare*, to make a review; because once in five years the censors reviewed the army.

LUSTRUM was also a ceremony, or sacrifice used by the Romans, after numbering their people, once in five years. See **LUSTRATION**.

The census was accompanied always by a lustration of the people, so the word *lustrum* has constantly been taken by the ancients and moderns for a term of five years: yet if we enquire into the real state of the case, we shall find no good ground for fixing so precise a signification to it; but, on the contrary, that the census and *lustrum* were, for the most part, held irregularly and uncertainly, at very different and various intervals of time, as the particular exigencies of the state required. Middlet. of Rom. Sen. p. 107.

LUTANGER, in *Geography*, a small island in the East India sea, near the S. coast of Mindanao. N. lat. 7° 19'. E. long. 123° 15'.

LUTATION, in *Chemistry*, is used for the cementing of chemical vessels close together.

LUTAYA, in *Geography*, one of the smaller Philippine islands, near the island of Panay.

LUTE, **LUTUM**, in *Chemistry*, a composition of certain tenacious substances, wherewith to close the apertures and junctures of vessels in distillation, &c. See **CEMENT**, **CEMENT**, and **MORTAR**.

LUTE, *Leuto*, Ital., *Laute*, Germ., a musical stringed instrument, of which, though the shape or sound is now hardly known, yet during the sixteenth and seventeenth centuries it was the favourite chamber instrument of every nation in Europe, and in the beginning of dramatic music the recitatives were accompanied by the arch-lute, or theorbo, instead of the harpsichord.

Sir Thomas Wyatt, the elder, one of our best early poets, has left us a sonnet to his lute, written very early in the sixteenth century; and Congreve, at the end of the seventeenth, has celebrated the performance of Mrs. Arabella Hunt on that instrument.

The earliest mention of the lute that we have found among the moderns is in Boccaccio, *Giornata prima*, where the singing is generally said to have been accompanied by the lute. In Chaucer's Pardoner's tale, we are told:

“ In Flanders whilom was a compaignie
Of younge folk that haunted in folie,

As hazard, riot, fiewis and tavernes
Whereas with harpes, lutes, and giternes,
They daunce and play.”

In Shakspeare's first part of Henry IV. Mortimer tells his lady, who can speak no English, that her tongue

“ Makes Welsh as sweet as ditties highly penn'd,
Sung by a fair queen in a summer's bower,
With ravishing division to her lute.”

And in lord commissioner Whitelocke's MS. narrative of a masque given in 1633, to Charles I. and his queen, by the four Inns of court, he says, that “ he engaged forty lutes, besides other instruments and voyces of the most excellent kind in consort.”

There was a lute at the Italian opera in England, to the end of Handel's regency. And the place of lutenist in the king's chapel was continued till the death of Gighier, about the middle of the last century.

It seems as if in France there had been a time when there was no other instruments in use than lutes, as *luthier* not only implies the maker of lutes, but violins, violoncellos, and other instruments of the same kind.

There has been no satisfactory etymology given to the word lute, though Scaliger and Bochart have tried to find or frame one, deriving it from the Arabic *allaud*, whilst others have derived it from the German *laute*, or *lauten*, sonare.

The stringed instruments of the ancients were so numerous, and so various in their forms, that we know not the precise difference between the lyre and cithara. The *testudo*, among poets, not only implies the lyre, said to have been originally made by Mercury of the back or hollow shell of the *testudo aquatica*, or sea tortoise, but music itself.

As to the different names that may have been given to the same kind of instrument by the ancients, such as *organyon*, *xylos*, *testudo*, *cithara*, &c. we shall leave the dispute, says Merlennus, to grammarians, who may consult Athenæus, Julius Pollux, Arislides, Quintilianus, and other Greeks; for since we are in possession of the instrument, they may give it what name they please.

Vincenzo Galileo (Dial.) says the best lutes were made in England.

The lute consists of four parts, the table, the body or belly, which has nine or ten fides, the neck or finger-board, which has nine or ten frets or divisions marked with catgut or bowel strings, and the head or cross, where the screws or pins for tightening or relaxing the strings in tuning are fastened. This is called the lute with two necks, or the theorbo, which has sometimes only one string to each note. In the middle of the belly or table, there is a rose or passage for the sound. There is also a bridge, to which the strings are fastened, and a piece of ivory between the head and the neck, to which the other extremities of the strings are fitted.

In performing on the lute, the strings are struck with the right hand, and pressed upon the frets with the left.

Whoever wish to teach themselves to play upon this instrument, as it will be difficult now to find a good master, may attain considerable knowledge in the practice of it by a perusal of Père Merfenne's *Harmonie Universelle*, printed at Paris in 1636, folio, *livre ii. des Instrumens*, p. 45; and Mace's *Musick's Monument*, folio, 1676, Grassineau. This last book is written in a style amusingly quaint; but it probably contains all the essential rules known at the time it was written, both for playing, judging of the goodness of the instrument.

instrument of strings, placing the frets, &c. But after the decease of honest Thomas Mace, whose style much resembles that of Anthony Wood, though he exceeds him in quaintness and simplicity, there were probably many refinements discovered by great players, both in composing for the instrument and in performing upon it, which are now quite lost.

The inhabitants of Congo have a lute of a singular kind. The body and neck of this instrument resemble ours; but the belly, that is, the place where the rose or sound-hole has place in our lutes, is of very thin parchment; which probably implies that the whole table or belly of this instrument is covered with parchment instead of wood. It is strung with the hair of an elephant's tail, the strongest and the best that can be chosen; or else with the bark of the palm-tree. The strings reach from one end of the instrument to the other, and are fastened to rings fixed at different places of the lute one above the other. To these rings are suspended small plates of iron and silver of different sizes and different tones. In thrumming the strings these rings are put in motion, which likewise move the little metal plates, and the whole forms a kind of murmuring harmony, or rather a confused noise, which is pretended not to be disagreeable. The inhabitants likewise add, that in thrumming the strings of this instrument in the way we produce sound from the harp, the musician expresses his thoughts as clearly as if he were speaking. *Encycl. Suppl. folio.*

LUTE. *Archi.* See **ARCILUTO**.

LUTE. *Theorbo.* See **THEORBO**.

LUTEA, in *Natural History*, the name of a species of fly found frequently near waters after rain; it is of a dunish-yellow colour, the wings are long, and the eyes large and prominent; the tail is thick, and has two hairs of a considerable length growing at the head, so that it is of the bifurcated kind.

LUTEA is also a name by which some authors have called the yellow-hammer. See **EMBERIZA Citrinella**.

LUTEFGUR, in *Geography*, a town of Hindoostan, situated in a pass between the mountains of Benares, where the air is very insalubrious; 15 miles S.E. of Chunar.

LUTEOLA, in *Botany*, the herb Weld, Dyer's-weed, or Yellow-weed, so called from *luteus*, yellow, because it is of very general use in various countries for giving that colour to woollen cloth or yarn. See **RESEDA**.

LUTEOLA, in *Ornithology*, a name given by many to a small bird, the *MORACHIA Trochilus* of Linnæus (which see), called by others *afflus*, and by others *regulus non cristatus*; but this last is a name that has occasioned some confusion, as many have erroneously called our common wren the *regulus*, and as it has no crest, imagined it to be the bird meant by this name.

It is, excepting the crested wren, the smallest of all European birds, and it very little exceeds that in size; its head, neck, and back are of a greenish-brown; the rump is greener than the rest; it has a yellow line on each side, extended from the nostrils, beyond the eyes, to the hinder part of the head; the breast, throat, and belly are yellow, with a very faint taint of green; the wings and tail are brown, and all their feathers are tipped with green at their ends: the under part of the wings has much of a very fine green; the beak is extremely slender, and half an inch long; the mouth is yellow within; it makes a loud noise, like that of a grasshopper, and is principally found among willows; it is continually creeping and singing among the branches of trees; it builds with straw and feathers, and lays five eggs, which are white, and spotted with red; there is a considerable variation in the colours of these birds; some of them being

much greener on the back, and much whiter on the belly than others.

LUTEREE, in *Geography*, a town of Hindoostan, in Lahore; 33 miles N. of Junamoo.

LUTHER, **MAURITZ**, in *Biography*, the celebrated author of the Reformation in Germany, descended from parents in very humble circumstances, was born at Eisleben, in Saxony, in the year 1483. He discovered an early inclination for learning, and having attained the rudiments of grammar under his father's roof, he was sent to school at Magdeburg, where he continued only about a year, and during that short period he supported himself, like many other poor German scholars, by literally begging his bread. From Magdeburg he went to Eisenach, in Thuringia, and distinguished himself in a school of high reputation, by his diligence and proficiency. In 1501 he was entered at the university of Erfurt, and in a very short time, having a mind superior to the scholastic modes of instruction then in use, he became disgusted with those subtle and unillustrative sciences. He immediately applied himself with the greatest ardour and assiduity to the works of the ancient Latin writers, such as Cicero, Virgil, Livy, Sallust, &c. and such was the success with which he studied, that he became the object of admiration to the whole university. He took his degree of M.A. when he was scarcely twenty years of age, and immediately afterwards began to read lectures on Aristotle's physics, on ethics, and other branches of philosophy. He began now to consider the profession which he should adopt for his support in life, and, by the persuasion of his friends, he turned his attention to jurisprudence; but an accident, to which he was witness, viz. the death of a friend by the discharge of a thunder-cloud, so sensibly affected him, that he determined to retire from the world into a convent of the Augustine friars. No entreaties on the part of his friends could divert him from his plan, which he conceived to be a duty that he owed to God, and accordingly assumed the habit of that order. He now applied himself very diligently to the study of theology, and turned his mind so eagerly to the reading of the Latin bible, which he had met with by accident, as to excite the most lively emotions of surprise and astonishment among the monks, who were little accustomed to derive their notions concerning religion from that source. Having passed a year in the monastery of Erfurt, he took the vows, and was, in 1507, admitted to priests' orders. His great and profound learning, the sanctity of his moral conduct, and his extensive knowledge of the holy scriptures, were generally known and applauded; and in the following year, Frederick, elector of Saxony, having lately founded an university at Wittenburg, appointed Luther to the professorship of philosophy, and afterwards that of divinity. The duties attached to these offices he discharged with so much ability, and in a method so totally different from the usual mechanical and dull forms of lecturing, that he was crowded with pupils from all quarters, and was regarded as the chief ornament of the university. In 1510, Luther was sent to Rome by the monks of his order, to get some disputes between them and their vicar-general settled by his holiness the pope. While in that city, he made his observations on the pope and the government of the church of Rome; he examined the manners of the clergy, which he severely censured, particularly as to the hasty and slovenly method which they adopted in performing divine service. The carelessness with which they were accustomed to offer up their prayers to Almighty God, he declares excited in his breast sentiments of astonishment and horror. As soon as he had accomplished the object of his mission he returned to Wittenburg, where, in 1512, he had

had the degree of doctor of divinity conferred upon him, at the expense of Frederick, elector of Saxony, who frequently attended his pulpit discourses, and was as delighted with his eloquence as satisfied with his extraordinary merits. Luther was, at first, desirous of declining the honour offered him, considering himself too young for such a distinction, but his objections were over-ruled, and he was told "that he must submit to be thus dignified, inasmuch as the Almighty had important services to be performed in the church, and through his instrumentality." Little did they, who made use of this expression, whether in a tone of seriousness or levity, imagine how truly its prophetic language should be verified, and how extensively useful his future labours should be, in clearing away the corruptions that had almost overwhelmed the Christian world, as it was then called; for real Christianity, as dictated by its meek and holy founder, was as difficult to be discerned in the age preceding the great reformer, as it was among the most barbarian nations devoted to the superstitious and idolatry of Greece and Rome.

Under the article REFORMATION, we shall endeavour to exhibit, in its true colours, the state of the papal dominion and church, both with respect to the people and clergy, as it existed when Luther began his labour; to develop the causes which produced so important a change in the world; and trace its consequences with regard to mankind. In the present article we shall more particularly confine ourselves to the life and labours of Luther himself.

This great man, almost as soon as he was created doctor of divinity, felt it incumbent on him to shew that the title and honour had not been conferred without reason. He applied himself with all diligence to the duties of the theological chair. He read lectures on the several books of the scriptures. He commented on the epistle to the Romans and on the book of Psalms, and his illustrations were so striking, that, by the thoughtful and the serious, he was regarded as the harbinger of a new day ready to break out after a long night of darkness and ignorance; and he led multitudes to think and to reason on matters of high importance who had never reflected or thought before beyond the concerns of the present world. He opposed, with a vehemence that could scarcely be withstood, the errors which had been long current in the church and the schools, as truth, saying that the scriptures were the only test of sound doctrine and practical morality. He applied himself diligently to the study of the scriptures, in their original languages, and encouraged the cultivation of these languages in the university, as the only sure foundation on which a proper knowledge of religion could be built. Luther was a strict disciplinarian in the college, but he exacted no more from the young men under his inspection than he shewed himself an example of in his own moral conduct: and thus, by uniting a practical regard to religious duties, with an earnest zeal in enforcing them upon the minds of others, he contributed, in an eminent degree, to raise the university of Wittemberg to a high degree of reputation, which amply gratified the elector for his munificence in founding it. He had himself been early initiated in the Peripatetic philosophy, then universally taught in the schools; but his eyes were soon opened to its numerous defects and silly subtleties, and while a professor at Wittemberg, in 1516, he wrote to Jodocus, a zealous Aristotelian, who had been his preceptor at Erfurt, stating at first only his doubts respecting the doctrines in which he had been instructed, and which, in his turn, it was expected he should teach others. Jodocus, wholly unprepared for such remarks, made with firmness, mingled with modesty, was highly incensed against the author of

them, and in his next visit to Erfurt refused to see him. Luther had not a mind to be intimidated: even the respect which he felt for the instructor of his early years forbade him to recede a single step; he had set his hand to the plough, and could not look back; he had embarked in the quest of reform, and must necessarily advance, notwithstanding the difficulties that might be opposed to him by his dearest friends. He accordingly wrote a second letter to Jodocus, in which he gave, as his decided opinion, ground upon indisputable evidence, that it would be impossible to reform the church, without entirely abolishing the canon, and decretal, and with them the scholastic logic, philosophy, and logic, and instituting others in their stead.

In early life, Luther, whose comprehensive mind could grasp all subjects, had studied the writings of St. Augustine, Thomas Aquinas, Duns Scotus, and other celebrated schoolmen; and in the dispute concerning Universities, attached himself to the party of the Nominalists, but neither age and reflection instructed him to treat the whole controversy with contempt. This has been referred chiefly to his early acquaintance with the ancients, but it was probably owing rather to that peculiar strength and ardour of mind which led him easily to discover the absurdity of the peripatetic modes of reasoning, and of judging upon theological and philosophical subjects, and to observe with resentment and indignation the fatal effects of corrupt philosophy united with ecclesiastical tyranny. Under the article LEO X. we have alluded to the general sale of indulgences published by that pontiff: this proved the first link in a chain of causes which produced a revolution in the sentiments of mankind, the greatest, as well as the most beneficial that has happened since the publication of Christianity. When Leo was raised to the papal throne, he found the revenues of the church exhausted by the vast projects of his predecessors: he felt no desire to pursue a system of economy; his heart, as we have seen, (see LEO X.) was set on aggrandizing his family: to this may be added his love of splendour, his taste for pleasure, and his munificence in rewarding men of genius and merit, all which involved him in new expenses; in order to provide a fund for which, he tried every device that himself and friends could invent, to drain the credulous multitude of their wealth. Hence the sale of indulgences, which pretended to convey to the possessor, either the pardon of his own sins, or the release of any one, already dead, in whose happiness he was interested, from the pains of purgatory. Leo had not, however, the credit of the invention of this system: it may be referred back to the papacy of Urban II. in the eleventh century, who had contrived the lucrative trade in order that the pope might have the means of recruiting those who went to join the army of the crusaders, in the Holy Land. They were afterwards granted to the pope, being unwilling to serve themselves, hired a soldier for that purpose, and in a short time they were beloved on such a scale, gave money for accomplishing any pious work enjoined by the holy pontiff.

Julius II. had bestowed indulgences on all who contributed towards building the church of St. Peter at Rome, which, as we have seen, was begun while he sat upon the papal throne, and as Leo was carrying on that expensive building, his grant was founded on the same pretence. The right of promulgating these indulgences in Germany, together with a share in the profits arising from the sale of them, was granted to Albert, elector of Mentz, and archbishop of Magdeburg, who, as his chief agent for retailing them in Saxony, employed Tetzel, a Dominican friar of licentious morals, who executed his commission with great audacity and success, but without regard to any principles of prudence.

or decency. At length the trade was carried on with so little attention to the interests of society, that it became a general wish that some check should be given to it. Luther was not an inattentive spectator: he beheld, with concern and indignation, the artifices of those who sold, and the folly or simplicity of those who purchased indulgences. Having examined the subject, and finding that the practice derived no countenance from the scriptures, he determined openly to protest against such scandalous impositions on his deluded countrymen.

In the year 1517, he attacked, with all the vehemence in his power, from the pulpit, in the great church of Wittenburg, the vices of those very monks who dared openly to distribute indulgences: he tried their doctrines by the standard of scripture, and exhorted his hearers to look for salvation to the means appointed by God in his holy word. The boldness and fervour with which he uttered his exhortations did not fail to make a deep and lasting impression on the people, who, suspecting the delusions to which they had been long subject, were ready to join any person, especially one whose character for integrity stood so high as Luther's, in throwing off a yoke which they were scarcely able to endure. Luther was not content with undeceiving the persons who crowded round his pulpit; he advanced with dignity to a higher authority; he wrote to Albert, elector of Mentz, and archbishop of Magdeburg, remonstrating against the false opinions, as well as the wicked lives, of the defenders and distributors of indulgences, entreating him, in a most supplicatory tone, to exercise the authority vested in him for correcting these evils. The archbishop was, however, too deeply interested in these abuses to lend a hand in putting an end to them. In addition to his letter, Luther transmitted to the prelate ninety-five theses, which he had proposed as subjects of inquiry and disputation, and which he had publicly fixed in a church at Wittenburg, with a challenge to the learned to oppose on a given day, either in person or by writing; and to the whole he added a solemn protestation of his profound respect for the apostolic see, and implicit submission to its authority. On the appointed day no person appeared to contest Luther's theses, which rapidly spread all over Germany, and excited universal admiration of the boldness which he discovered in venturing to call in question the papal power and authority, and to attack the Dominicans, armed, as they were, with all the terrors of the inquisitorial authority. The friars of his own order were delighted with his invectives against the monks who sold indulgences, and were anxious to see them exposed to the hatred and scorn of the people; and he was secretly encouraged in his proceedings by his sovereign, the elector of Saxony, who thought they might contribute to give some check to the exactions of the court of Rome, which the secular princes had been long unsuccessfully endeavouring to oppose. The publication of Luther's theses brought into the field many zealous champions in defence of the holy church, who were less eager for the dissemination of the truth, than for the profits which existing abuses afforded them, and who accordingly traduced the character of Luther, endeavouring to excite the indignation of the clergy and populace against him. Luther, however, was not to be terrified by any measures which his present adversaries could adopt: he found a large body of the people adhering to his doctrines, and he was content, in their behalf, to go through evil report as well as good report: he even went so far, in a public declaration, as to say, "that if the pope and cardinals entertained the same opinions with his opponents, and set up any authority against that of scripture, there could be no doubt but that Rome was itself the very seat of antichrist, and that it

would be happy for those countries which should separate themselves from her."

It does not appear that, at this early period, Luther had any intention of setting himself against the power of the pope; he even wrote a letter to his holiness in the most respectful terms, shewing the uprightness of his intentions, and the justice of the cause of which he was the advocate. Shortly after this, by the incessant representations of Luther's adversaries, that the heretical notions he was propagating threatened the most fatal mischiefs to the interests of the church, Leo issued an order for his appearing at Rome to justify himself. The judges of his conduct were already appointed and selected on account of their hostility to him. The reformer, by means of his own petitions, and the interference of those friendly to his cause, was allowed to be heard at Augsburg, instead of being obliged to travel to Rome. Even here, his avowed enemy, cardinal Cajetan, was appointed to try the merits of the question. Luther arrived at Augsburg in the month of October, 1518, and was immediately admitted into the presence of the cardinal, who, in their several interviews, would not condescend to argue the matter with a person of such inferior rank: but, by the mere dictate of authority, required Luther, by virtue of the apostolic powers with which he was invested, to retract the opinions which he had advanced, and to submit, without hesitation, to the judgment of the pope. Luther, though, for the moment, surprised at the demand of recantation, declared that he could not, with a safe conscience, renounce opinions which he believed to be true, nor should any consideration induce him to do what would be so base in itself and so offensive to God: still, however, he declared his readiness to submit to the lawful determination of the church. He went much farther: he expressed a willingness to refer the controversy to certain universities which he named, and promised neither to write nor preach concerning indulgences, provided the same silence with respect to them were enjoined on his adversaries. These offers were rejected by the cardinal, who peremptorily insisted upon a simple recantation, and, at the same time, forbade the reformer to enter again into his presence, unless he came prepared to comply with what he required. As he had no intention to submit, he thought it more prudent to withdraw, which he did in as private a manner as possible, having first prepared a formal and solemn appeal from the pope, who was then ignorant of his cause, to the pope, at a time when he should have received more full and explicit information with respect to it.

The sudden departure of Luther enraged the papal legate, who wrote to the elector of Saxony, requiring him to withdraw his protection from so seditious a person, and either to send him prisoner to Rome, or to banish him from his territories. The elector refused to comply with either of these requests, though with many external professions of esteem for the cardinal; but he at the same time assured Luther privately, that he would not desert him. Being thus ably supported, Luther continued to vindicate his opinions, and he gave a challenge to all the inquisitors to come and dispute with him at Wittenburg, promising them not only a safe conduct from the elector, but liberal entertainment, free from all expences, while they continued at that place. In the mean time Leo's ambition urged him to issue a bull, by which he attempted, by his papal authority, to put an end to the dispute about indulgences, and in this public paper, he magnified, almost without bounds, the efficacy of indulgences, and imperiously commanded all Christians to assent to what he delivered, as the doctrine of the Holy Catholic church. Luther was now satisfied that the storm would speedily fall upon him, and therefore had recourse

recourse to the only expedient left him, to ward off the effect of papal censures, by appealing from the pontiff to a general council, which he maintained to be superior in authority to the pope. In January 1519 the emperor died, which rendered it expedient for the court of Rome to suspend any direct proceedings against Luther; for by this event, the vicariat of that part of Germany, which is governed by Saxon laws, devolved on the elector of Saxony, and was executed by him during the interregnum which preceded the election of the emperor Charles V. Under the administration of this prince, Luther enjoyed tranquillity, and his opinions were suffered to take root, and even to grow up with some degree of strength and firmness.

Leo now hoped he should be able to bring back Luther to submission and obedience, without having recourse to harsh measures. He accordingly fixed on Charles Miltitz, a Saxon knight, a person endowed with much prudence and dexterity, whom he sent into Saxony, as his legate, to present the elector with a golden consecrated rose, as a mark of peculiar distinction, and also to treat with Luther about the means of reconciling him to the court of Rome. Miltitz, by his great address and soothing manners, and his encomiums on Luther's character, produced a considerable effect on his mind, and he made such concessions as proved, that his principles as a reformer were by no means steadily fixed. He agreed to observe a profound silence on the subject of indulgences, provided his adversaries were bound to the same measures; and he wrote a humble and submissive letter to the pope, acknowledging he had carried his zeal and animosity too far; and he even consented to publish a circular letter, exhorting his followers and adherents to reverence and obey the dictates of the Holy Roman church.

Had the court of Rome been sufficiently prudent, and accepted this submission of Luther, and prevented its own champions from engaging in the field of controversy, the cause of the reformation would have been lost. But the inconsiderate zeal of some of Luther's opponents, renewed the divisions which were so nearly healed, and obliged Luther and his followers to examine deeper into the enormities which prevailed in the papal hierarchy, as well as the doctrines of the church. During this year a famous controversy was carried on at Leipzig, on the challenge of Eckius, between himself and Carlstadt, concerning the freedom of the will, and at the same time he urged Luther to enter the lists with him, on the subject of the pope's authority and supremacy. The challenge was accepted, and on the appointed day the three champions appeared in the field. The assembly which met to witness the combat was numerous and splendid, and each of the combatants conducted himself with great skill and dexterity; in the course of the debate, Luther no doubt was carried farther than he dreamed of going, led on from one argument to another: he at length maintained, that the church of Rome, in the earlier ages, had never been considered as superior to other churches, and combated the pretensions of that church and its bishop, from the testimony of scripture, the authority of the fathers, and the most approved ecclesiastical historians, and even from the decrees of the council of Nice, while the best arguments of his adversary were derived from spurious decretals, none of which could boast of an antiquity equal to that of four centuries. Hoffman, the president, refused to declare on which side victory had fallen, and the question was referred to the universities of Paris and Erfurt. Eckius clearly saw that the auditors generally declared in favour of the arguments made use of by his adversary, and from this moment he breathed fury and revenge against Luther. The latter had, however, the happiness to know, that he had

convinced the celebrated Philip Melancthon, at that time professor of the Greek, at the university of Wittenburg, of the justice of his cause, and he soon after found a vigorous auxiliary in Ulric Zuingli, a canon of Zurich, in Switzerland, whose extensive learning and uncommon sagacity were accompanied with the utmost intrepidity and resolution. The party of reformers now was great in the talents, and illustrious in the characters of their leaders, who made, at this period, the utmost efforts to draw over Erasmus to their side. The reputation and authority of this great scholar were of the highest weight in Europe, as well on account of his talents as of his strictures upon the errors of the church, and upon the ignorance and vices of the clergy. He had sown the seeds which Luther cherished and brought to maturity, but was, however, too wary to entangle himself so deeply in the dispute as to lead him into any danger. About this time the universities of Cologne and Louvain took part against Luther, against whose decrees he immediately wrote with his usual spirit and intrepidity. Eckius likewise repaired to Rome, intent on accomplishing the ruin of Luther, and he thought he had performed the deed when, by his exertions and influence, pope Leo assembled the college of cardinals to prepare a sentence against him with such deliberation, as it was hoped no exception could be taken, either with regard to form or matter.

On the 15th of June 1520, the bull was issued, in which forty-one propositions, extracted from Luther's works, were condemned as heretical and scandalous, and all persons were forbidden to read his writings on pain of excommunication; those who possessed any of them were commanded, under severe penalties, to commit them to the flames. Luther himself, if he did not within sixty days publicly recant his errors, and burn his books, was pronounced an obstinate heretic, excommunicated, and delivered unto Satan for the destruction of the flesh; and all secular princes were required, under pain of incurring the same censure, to seize his person, that he might be punished as his crimes should be found to merit. Short-sighted priests, and rash bigots, contemplated in this sentence the ruin of Luther, and the termination of those principles which he had espoused; but it has proved fatal only to the church which uttered it, and to the cause which it was intended to support. When an account of what had happened was brought to Luther, he was neither disconcerted nor intimidated, but calmly consulted the most proper means of present defence, and future security. He appealed a second time to a general council, and came to the resolution of voluntarily renouncing communion with the church of Rome, and in justification of his own conduct, which he might well expect would be every where, though not by all persons, condemned, he exposed to the world, without the least disguise or ceremony, the abominable corruptions and delusions of the papal hierarchy; he went still farther, and without hesitation declared, in the most solemn manner, before the whole world, that the pope was the predicted "man of sin," the anti-christ set forth in the writings of the New Testament. Being now released from all obedience to the pope, and setting himself up in opposition to his power, he declaimed, without scruple, against his tyranny, and he exhorted all Christian princes to shake off the ignominious yoke, which had been so long imposed on them, but the weight of which neither they nor their fathers could well bear. He made it the theme of his joy and exultation, that he was marked out as an object of ecclesiastical indignation, because he had ventured to assert and vindicate the liberty of mankind. Luther proceeded from words to acts; Leo had burnt the books of Luther, and he, by way of returning the compliment, assembled all

the professors and students of the university of Wittenburg, and with much ceremony, in the presence of a prodigious multitude of people of all ranks and orders, committed to the flames the pope's bull, and the decretals and canons relating to his supreme jurisdiction: the example was soon followed in several cities of Germany. He next collected from the canon law some of the most extravagant propositions with respect to the omnipotence of the papal power, and the subordination of all secular jurisdiction to the authority of the holy see, which he published with a commentary, pointing out the impiety of such tenets, and their evident tendency to subvert all civil government. Within a month after this, a second bull was issued against him, by which he was expelled from communion with the church, for having insulted the majesty, and disowned the supremacy of the Roman pontiff. The intimidating power of papal condemnation had now lost its effect in Germany, and the bull of Leo put his antagonist upon the project of founding a church upon principles directly opposite to those of Rome, and to establish in it a system of doctrine and ecclesiastical discipline, more consonant with the spirit and precepts of the gospel.

From this time Luther never ceased to attack the corruptions of the church of Rome, and his reasoning made deep impressions upon the minds of the people; their respect and reverence for ancient institutions and doctrines in which they had been educated were shaken. Students crowded from all parts of the empire to Wittenburg, and under Luther, Melancthon, Carlostadt, and other eminent, and, for the time, truly enlightened professors, imbibed principles, which, on their return, they propagated among their countrymen with zeal and ardour. On the arrival of Charles V. in Germany, the first act of his administration was to assemble a diet of the empire at Worms. This meeting was fixed for the sixth of January 1521; in the circular letter to the different princes, the emperor informed them that the express purpose of this meeting, was to concert with them the proper measures for checking the progress of those new and dangerous opinions, which threatened to disturb the peace of Germany, and overthrow the religion of their ancestors. At the same time the pope gave notice to the elector of Saxony, of the decree which he had issued against the heresies of Luther, and requested that he would so far concur with him as to cause all the writings of Luther to be publicly burnt, and that he would either put the author of them to death, or imprison him, or at least send him to Rome. He sent a similar message to Wittenburg, but neither the elector nor the university paid any attention to the exhortations of his holiness. To the elector of Saxony Luther was under infinite obligations, as by him alone was the emperor prevented from taking steps, which would have been fatal to the progress of his cause. As soon as the diet was assembled at Worms, the papal legates insisted that they were bound, without deliberation, to condemn a man whom the pope had already excommunicated as an obstinate heretic. The emperor in this was ready to acquiesce, but the elector again stepped forth in defence of Luther, and not only prevented the publication of any unjust edict against him, but insisted that he ought to have his cause tried by the canons of the Germanic church, and the laws of the empire. It was therefore resolved, that Luther should be summoned before the diet, and be allowed a hearing before any final sentence should be pronounced against him. To protect him against the violence of his enemies, the emperor, and all the princes through whose territories he was to pass, granted him a safe conduct, and Charles himself wrote to require his immediate

attendance, renewing, in the most solemn manner, his assurances of protection from injury or ill-treatment. Luther had no sooner received the summons than he prepared to obey it. Nor could the remonstrances of his friends prevent him from running the risk of being treated as his books had been already treated. Some of them, anxious for his safety, reminded him of the fate of the celebrated Huss under similar circumstances, and protected by the same security of an imperial safe-conduct, and filled with solicitude, advised and entreated him not to rush wantonly into danger. But Luther with calmness and dignity replied, "I am lawfully called to appear at Worms, and thither will I go in the name of the most high God, though as many devils, as there are tiles on the houses, were there combined against me."

On the 16th of April Luther arrived at Worms, where greater crowds are said to have assembled to behold him, than had ever appeared at the emperor's public entry. While he continued in that city, he was not only treated with respect, but his apartments were resorted to by persons of high rank, and by the princes of the empire. Before the diet he behaved with becoming respect; he acknowledged that he had sometimes been carried away by the ardour of his temper, and that the vehemence of his writings could not always be justified. While, however, he readily admitted his errors, he shewed no inclination to renounce a single important principle which he had been promulgating, and he displayed the utmost presence of mind when he was called on to plead his cause before the grand assembly, on the 17th and 18th of April. That his reasonings should not change the minds of those who came to condemn, cannot be a matter of surprize, but when he was called on to recant, he solemnly declared, that he would neither abandon his principles, nor materially change his conduct, unless he were previously convinced, by the scriptures, or the force of reasoning, that his sentiments were erroneous and his conduct unlawful. Enraged at his unbending spirit, some of the ecclesiastics proposed, notwithstanding the promises made to the contrary, to avail themselves of the opportunity of having an enemy in their power, to deliver the church at once from such a pestilent heretic. But the members of the diet and the emperor also refused to act in a manner that must blast their character for ever with the world, and Luther was permitted to depart in safety. Scarcely, however, had he left the city, when, in the emperor's name, and by the authority of the diet, he was, in a most severe edict, pronounced an obstinate heretic, a member cut off from the church, deprived of the privileges which he had enjoyed as a subject of the empire, and the severest punishments were denounced against those who should receive, entertain, or countenance him, either by acts of hospitality, by conversation, or writing, and all were required to concur in seizing his person, as soon as the term of his safe-conduct expired. This decree produced scarcely any effect; the emperor was too much engaged by the commotions in Spain, and in the wars in Italy and the Low Countries, to attend to Luther, and the sovereign princes who had not been present at the diet, and who felt for the liberties of the empire, and the rights of the Germanic church, treated it with the highest indignation, or the utmost contempt. Luther was still, to the elector of Saxony, the object of his most anxious solicitude; and the measures which he adopted at this critical juncture, effectually secured him from the threatening storm. In consequence of a preconceived plan, and, as some historians have imagined, not without the knowledge of the emperor, as Luther was on his journey, near Eisenach, a number of horsemen in masks rushed out of a wood, and surrounding his company, carried

ried him off with the utmost speed to the castle of Wartenburg. There the noble-minded elector ordered him to be supplied with every thing that he could want, but the place of his retreat was kept a profound secret. The sudden disappearance of Luther not only occasioned the most bitter disappointment to his adversaries, but rendered them doubly odious to the people of Germany, who, not knowing what was become of their leader in reformation, conjectured a thousand things, till at length they were ready to give him up as destroyed by the fury of his enemies. Luther was, however, living in peace, and in the enjoyment of whatever was necessary to his well being and to his amusement; he was frequently indulged with the exercise of hunting in the company of those who had the charge of him, living in this retirement under the name of Yonker George. During the period of his solitude, he translated a great part of the New Testament into the German language, wrote and published tracts in defence of his doctrines, which, as soon as they were seen, revived and animated the spirit of his followers, and wrote frequent letters to his friends; he had also, during this period, the satisfaction of knowing that his opinions were gaining ground, and that they had already made some progress in almost every city in Saxony. Luther, weary at length of his retirement, appeared publicly at Wittenburg, in March 1522: this step he took without the elector's knowledge or consent, but he immediately wrote him a letter to prevent the possibility of his taking offence, assigning as a reason, that it was in consequence of the information which he had received of the proceedings of Carlostadt, one of his disciples, who was animated with similar zeal, but possessed less prudence and moderation than his master. This person, in the absence of Luther, had attempted to abolish the use of masks, to remove images out of the churches, to set aside auricular confession, the invocation of saints, and in short had quite changed the doctrine and discipline of the church at Wittenburg, all which Luther said was unseasonably and rashly done. At this time the doctrines of the reformer were not known in France; and in England, the sovereign, Henry VIII., had made the most vigorous exertions to prevent them from invading his realms: he even undertook to write them down, in a treatise entitled "Of the Seven Sacraments," &c. This work he presented to Leo X. in October 1521. The pope was so well pleased with the royal attempt to confute the arguments of Luther, that he complimented him with the title of "Defender of the Faith." Whatever respect and reverence Luther might shew to kings as such, he had none for the arguments of an antagonist, though armed with royal authority, and answered Henry with much severity, treating his performance in the most contemptuous manner. Luther now published his translation of the scriptures, which produced sudden, and almost incredible effects on the people of Germany, and proved more fatal to the church of Rome than all his other works. It was read with the utmost avidity by persons of every rank, who, with astonishment, discovered, how contrary the precepts of Christ are to the inventions of his pretended vicegerents, and being in possession of the rule and standard of faith, they conceived themselves qualified to judge of established opinions, and to pronounce when they were conformable to that standard. About this time, several imperial cities in Germany abolished the masks, and the other superstitious rites of popery, and openly embraced the reformed religion. The elector of Brandenburg, the dukes of Brunswick and Lunenburg, and the prince of Anhalt, became avowed patrons of Luther's opinions, and countenanced the preaching of them in their territories. Luther now made open war with the pope and bishops, and to render them as

despicable as possible, he wrote one book against the pope's bull, and another against the order falsely called the order of the bishops. The same year he wrote to the assembly of the states of Bohemia, in which he assured them that he was labouring to establish their doctrine in Germany, and exhorted them not to return to the communion of the church of Rome. Ferdinand, archduke of Austria, the emperor's brother, promulgated a very severe edict against the translation of the scriptures, and forbade all the subjects of his imperial majesty to possess any copies of it, or of Luther's other works. In this state of things Leo X. died, and was succeeded on the papal throne by Adrian VI., who immediately concerted measures with his cardinal concerning the best means for stopping the progress of heresy. The diet of the empire was holden soon after at Nuremberg, to which Adrian sent his brief, in which he observes, that he had heard with grief and indignation, that Martin Luther continued to teach the same errors, and to publish almost daily books full of heresies; that it appeared strange to him that so large and so religious a nation could be seduced by a wretched apostate friar; that nothing, however, could be more pernicious to Christendom, and that he therefore accordingly exhorts them to use their utmost endeavours to make Luther, and the authors of these tumults, return to their duty; or, if they refuse and continue obdurate, to proceed against them according to the laws of the empire.

The admonitions of his holiness produced no effect whatever, and the disciples of Luther advanced in their career with exultation and triumph. In 1523, Luther published several pieces; among these were some on the monastic life, which he attacked with great severity, and his exhortations, united with much strong satire, produced important effects, for soon after nine nuns, among whom was Catharine de Bore, whom he afterwards married, eloped from a nunnery and came to Wittenburg, an act that was as highly applauded by the reformer, as it was condemned by the devotees to the Roman church. Luther compares the deliverance of these nuns from the slavery of monastic life to that of the souls which Christ had delivered by his death. This year two of the followers of Luther were burnt at Brussels, and these were the first who suffered martyrdom for his cause: and about the same time that this tragical event was perpetrated, he wrote a consolatory letter to three noble ladies at Misnia, who were banished from the duke of Saxony's court at Eriburg, for reading his books.

On the death of Adrian VI., Clement VII. who succeeded him, sent a legate to the diet which was to be held at Nuremberg, to urge the necessity of a speedy execution of the edict of Worms: he was unsuccessful in the object of his mission, and found that the German princes, in general, were not at all inimical to the reformation; he accordingly retired to Ratisbon with the bishops, and those of the princes who adhered to the cause of Rome, where they engaged vigorously to execute the edict of Worms in their respective dominions. It was in the course of this year that the controversy between Erasmus and Luther on the doctrine of "free-will" commenced. Erasmus had been long urged to take up his pen against the reformer, though it was with the greatest reluctance that he yielded to the importunities of the pope and Catholic princes, suspecting that it would not be found the best mode of ending the differences, and establishing the peace of the church. At length he stood forward in defence of the doctrine of free-will, being desirous to clear himself from the suspicion of favouring a cause, which he would not wish to be thought in any way to favour. His book was entitled a "Conference concerning Free-will," which was written with much moderation, and without per-

sonal reflections. To soften the anger of Luther, he says in his preface, "That he ought not to take it ill that he differs from his opinions in particular points, as he had allowed himself the liberty of differing from the judgment of popes, universities, and doctors in the church." It was some time before Luther took up his pen in defence of his own positions, but his answer was extremely severe: he accused his opponent of "being careless about religion, and little solicitous what became of it, provided the world continued in peace, and that his notions were rather philosophical than dictated by Christian truth." Luther was next engaged in a controversy with Carlostadt, respecting the eucharist. Though Luther had renounced the doctrine of "transubstantiation," according to which the bread and wine were changed by consecration into the body and blood of Christ, yet he thought that the partakers of the Lord's supper received in some mystical way, with bread and wine, the real body and blood of Christ. This doctrine obtained the name of "consubstantiation." Carlostadt, who, as we have seen, was the disciple of Luther, maintained that the body of Christ was not actually present, but that the bread and wine were no more than external signs, or symbols, designed to excite in the minds of Christians the remembrance of the sufferings and death of Christ, and of the benefits which arise from them. This opinion was universally embraced by all the friends of the reformation in Switzerland, and by a considerable number of its votaries in Germany, but it was the commencement of a controversy that was carried on with much bitterness, which, notwithstanding the endeavours that were used to reconcile the contending parties, terminated at length in a fatal division between those who had embarked together in the sacred cause of religion and liberty, and which contributed to retard the progress of the reformation.

In the month of October 1524, Luther threw off the monastic habit, which, though not premeditated and designed, was regarded as a very proper introduction to a step which he took the following year, *viz.* his marriage to Catharine, the person already referred to, who had eloped from the nunnery of Nimptchen. This measure exposed him to much obloquy from his own friends, as well as from the Catholics. He was even ashamed of it himself, and acknowledged that it had made him so despicable, that he hoped his humiliation would give joy to angels, and be the source of vexation to devils. Melancthon found him so much afflicted with his past conduct, that he wrote some letters of consolation to him. It was not, it was said, so much the marriage, as the circumstances of the time, and the precipitation with which it was done, that occasioned the censures passed upon Luther. He married suddenly, and at a time when Germany was groaning under the miseries of a war which had been occasioned by the introduction of the new doctrines, and which will be noticed under the article REFORMATION. Luther soon recovered from the state of abasement into which he had for a season fallen, and then assumed his former air of intrepidity, and boldly supported what he had done. "I took," said he, "a wife, in obedience to my father's commands, and hastened the consummation, to prevent impediments, and stop the tongues of slanderers."

About this period Luther lost by death his friend, and the fast friend of the reformation, Frederic, elector of Saxony; but the blow was less sensibly felt, as he was succeeded by his brother John, a more avowed and zealous, but less able, patron of Luther and his doctrines. Frederic had been a kind of mediator between the Roman pontiff and the reformers of Wittenburg, and had always entertained the hope of restoring peace in the church, and of so recon-

ciling the contending parties, as to prevent a separation either in point of ecclesiastical jurisdiction or religious communion: hence, though rather favourable to the innovations of Luther, he took no pains to introduce any change into the churches of his own dominions, nor to subject them to his jurisdiction. But his successor acted very differently: he ordered a body of laws relating to the form of ecclesiastical government, the method of public worship, the rank, offices, and revenues of the priesthood, and other matters of that nature, to be drawn up by Luther and Melancthon, which he afterwards promulgated throughout his dominions. The example of this prince was followed by all the other princes and states of Germany, who renounced the papal supremacy and jurisdiction. The Lutherans were now threatened with a grievous persecution, which the public troubles of Europe only prevented from being carried into execution: they, on the other hand, were not negligent in taking effectual measures for defending themselves against the superstition and violence of their adversaries, and formed the plan of a confederacy for that prudent purpose.

In June 1526, a diet of the empire was held at Spire, at which Ferdinand, the emperor's brother, presided; Charles being fully occupied with the troubles in Spain and Italy. When the state of religion came before the assembly, the emperor's ambassadors used their utmost endeavours to obtain a resolution, that all disputes about religion should be suppressed, and that the sentence which had been pronounced at Worms against Luther and his followers should be put into rigorous execution; but it was agreed, that they could not execute that sentence, nor come to any determination with respect to the doctrines by which it had been occasioned, before the whole matter was submitted to the cognizance of a general council, lawfully assembled. An address to the emperor was unanimously agreed on, beseeching him to assemble, without delay, a free and general council; and it was also resolved, that, in the mean time, the princes and states of the empire should, in their respective dominions, be at liberty to manage ecclesiastical matters in the manner which they should think expedient; yet so as to be able to give an account of their administration to God and the emperor. This was a resolution the most favourable to the cause of Lutheranism; and several potentates, whom the dread of persecution had hitherto prevented from declaring for the reformation, being now delivered from their restraint, renounced publicly the superstition of Rome, and introduced among them the same form of religious worship, and the same system of doctrine, which had been received in Saxony. Luther and his fellow-labourers, in the mean time, by their writings, their instructions, their admonitions, and counsels, were carrying on their great cause with a spirit suitable to the importance and greatness of their undertaking. But this encouraging state of affairs was not of long duration: the emperor began to take measures for the recovery of those prerogatives which had been snatched from his predecessors, and which were necessary to the promotion of his ambitious schemes. For this purpose, he regarded it as necessary to suppress opinions, which might form new bonds of confederacy among the princes of the empire, and unite them by ties stronger and more sacred than any political connection. He accordingly resolved to employ all the means in his power for the full establishment of the religion, of which he was regarded the natural protector; considering this as the instrument by which he could extend his civil authority. He appointed, for this purpose, a diet of the empire to be held at Spire, in the spring of 1529, for the express purpose of taking into consideration the state of religion. In that diet the archduke Ferdinand presided, and

and had the address to procure a majority approving a decree, which declared it unlawful to introduce any change in the doctrine, discipline, or worship of the established religion, before the determinations of a general council were known. This decree was exceedingly revolting to the elector of Saxony, and other princes, as well as to the deputies of fourteen imperial cities, who, in a body, when they found their arguments and remonstrances of no avail, entered their solemn *protest* against it, on the 19th of April 1529, and appealed to the emperor and a future council. On this account they were distinguished by the name of PROTESTANTS, which, from this period, has been applied to all sects of whatever denomination which have separated themselves from the Roman church. The protesting princes sent embassies to the emperor, which were ill received; and in answer to one of them, they received an account that he was determined to come into Germany, with a view to terminate, in a diet to be held at Augsberg, in June 1530, the religious disputes which had produced so many and grievous divisions in the empire. Charles had many consultations with pope Clement VII. concerning the most effectual means for that purpose. In these interviews the emperor insisted, in the most urgent manner, on the necessity of assembling a general council: to this his holiness was a decided enemy, because he had learnt from history that general councils were factious, un governable, and slow in their operations; and he contended that the surest way was for the emperor to do his duty, in supporting the authority of the church, and in employing all his power in executing speedy vengeance on the obstinate heretical factions, who dared to call in question the authority of the holy Roman see. Charles was still for mild and conciliatory measures, but promised if these should prove ineffectual, that then he would employ the weight of his authority in reducing the rebellious to implicit obedience. In his journey to Augsberg he had full opportunity of knowing the sentiments of the people, and, from his own observation, he was satisfied that severity ought not to be attempted, until other measures proved ineffectual: he therefore called on the elector of Saxony to obtain from Luther, and other eminent divines, a written explication of their religious system, and an explicit avowal of the several points in which they differed from the church of Rome. Luther delivered to the elector at Torgaw seventeen articles, called "The articles of Torgaw," which were deemed by him a proper declaration of the sentiments of the reformed. By others they were not thought sufficiently open, and Melancthon was desired to give an account of the same, who, with a due respect to the sentiments of Luther, expressed his opinions, and set forth his doctrine, with the greatest elegance and perspicuity, and in terms as little offensive as possible to their opponents. Such was the origin of the creed, celebrated in history as "The confession of Augsberg." In June 1530, the diet was opened; and in a few days, the Protestants, who had adopted the opinions of Zuingli, delivered their confession, drawn up by Martin Bucer. A refutation of this was undertaken by Faber, Eckius, and Cochleus, which was read publicly in the diet; and the unlimited submission of the Protestants to the doctrines contained in it was required by the emperor. Instead, however, of yielding obedience to the imperial command, they demanded a copy of the paper, in order that they might have an opportunity of demonstrating more fully its extreme insufficiency and weakness. This request was refused, and there was now no prospect of a reconciliation. The emperor next attempted to bring over to his views the princes who had been sometime the patrons of the new doctrines: but however desirous

they might be of obliging the emperor, they would not make sacrifices to him of their integrity, and, in a firm tone, refused to abandon what they deemed the cause of God, for the sake of any earthly acquisition. The emperor, disappointed and exceedingly vexed, resolved to take vigorous measures for asserting the authority and doctrines of the established church, and enforcing the submission of heretics. He accordingly condemned the peculiar tenets held by the Protestants, forbidding any person to protect or even tolerate such as taught them, enjoining a strict observance of the established rites, and prohibiting any further innovation under severe penalties. This decree, which was regarded as a prelude to the most violent persecution, convinced the Protestants that the emperor was resolved on their destruction; and the dread of the calamities which were ready to fall on the church oppressed the spirit of Melancthon, who resigned himself to a settled melancholy. Luther, however, was not at all disheartened, and used his utmost efforts to keep up the spirits of those who were willing to give way; being assured that their personal safety, as well as success, depended wholly on union. In pursuance of this opinion, they assembled in 1530, first at Smalcald, and afterwards at Frankfort, where they formed a solemn alliance and confederacy, with the resolution of defending vigorously their religion and liberties against the dangers with which they were threatened by the edict of Augsberg. They invited the kings of England, France, and Denmark, to join in the confederacy; and, by their negotiations, secured powerful protection and assistance, in case of necessity. Luther was at first averse from this confederacy, dreading the calamities which it might produce. In this state of things, the elector palatine and the elector of Mentz offered their mediation, and endeavoured to reconcile the contending princes; and, in a short time, negotiations were carried on, that finally produced a pacification, the terms of which were agreed upon at Nuremberg, and solemnly ratified in the diet at Ratibon, August 3d, 1532. By this treaty, the Protestant princes engaged to assist the emperor with all their forces, in resisting the invasion of the Turks; and it was stipulated that universal peace should be established in Germany, until the meeting of a general council, the convocation of which the emperor was to endeavour to procure within six months; that no person should be molested on account of religion; that a stop should be put to all processes begun by the imperial chamber against the Protestants; and that the sentences already passed to their detriment should be declared void.

Luther now had the satisfaction and happiness of seeing one of the chief obstacles to the undisguised profession of his opinions removed; and henceforth he might sit down and contemplate the mighty work which he had accomplished: his disciples and followers, the Protestants of Germany, who had hitherto been regarded only as a religious sect, came to be considered as a political body of some consequence. The emperor, in conformity to the stipulations of the truce lately concluded, applied to the pope for a general council: but Clement threw a multitude of obstacles in the way to prevent it; and when he found that to be impossible, he insisted that the meeting should be held in Italy, but the Protestants contended for it in Germany. The latter insisted that all matters in dispute should be determined by the words of Scripture alone: the pope asserted that the decrees of the church and the opinions of the fathers were of equal authority. They required a free council, in which the divines, commissioned by different churches, should be allowed a voice; he aimed at modelling the council in such a manner as would render it entirely dependent on his pleasure.

Above

Above all, the Protestants thought it unreasonable that they should bind themselves to submit to the decrees of a council, before they knew on what principles those decrees were founded, by what persons they were to be pronounced, and what forms of proceeding they would observe. The pope maintained it would be unnecessary to call a council, unless those who demanded it previously declared their resolution to acquiesce in its decrees. The meeting was accordingly postponed during the pontificate of Clement VII.

In 1533 Luther wrote a consolatory epistle to some persons who had suffered hardships for adhering to the Augsburg confession of faith, in which he says, "The devil is the host, and the world is his inn; so that wherever you come, you will be sure to find this ugly host." He had also, about this time, a terrible controversy with George, duke of Saxony, who had such an aversion to the doctrines promulgated by Luther, that he obliged his subjects to take an oath that they would never embrace them. At Leipzig there were found sixty or seventy persons, who could not be restrained within the boundaries of the established creed, and it was discovered that they had consulted Luther about it; upon which the duke complained to the elector, that Luther had not only abused his person, but had preached up rebellion among his subjects. Luther refuted the accusation, by proving that he had been so far from stirring up his subjects against him, on the score of religion, that he had exhorted them rather to undergo the greatest hardships, and even suffer themselves to be banished. In the following year, the bible, translated by Luther into the German, was first printed, with the privilege of the elector; and it was published the year after. He likewise gave to the world a book against masses, and the consecration of priests, in which he relates a conference which he had with the devil upon those points: for it is a circumstance worthy of observation, that, in the whole history of this great man, he never had any conflicts of any kind, but the devil was always his antagonist. In 1535 the new pope Paul III. was applied to for a general council; and in the hope of preventing it, he appointed Mantua as the proper place. To this some of the Catholic sovereigns, and all the German Protestants, strongly objected; being fully persuaded that, in such a council, nothing would be concluded but what would be agreeable to the sentiments and ambition of the pontiff; and they demanded the performance of the emperor's promise, that they should have a council in Germany. At the same time, that they might not be taken by surprise, they desired Luther to draw up a summary of their doctrine, in order to present it to the assembled bishops, if it should be required of them. This summary, which was distinguished by the name of "The articles of Smalcalde," from the place at which they were assembled, is generally joined with the creeds and confessions of the Lutheran church. While our reformer was busily engaged in this work, he was seized with a grievous and very painful disease, a tit of the stone and obstruction of the urine, which continued so long as to give his friends serious apprehensions for his life. In the midst of his agonies, and after eleven days' torture, without the smallest relief, he set out, contrary to the advice of his friends, on his return home. The motion of the carriage, which it was expected would prove fatal to him, was the cause of removing the evil under which he was labouring. In the year 1538, as a general assembly seemed impracticable, the pope, that he might not seem to neglect that degree of reformation which was unquestionably within his power, deputed a certain number of cardinals and bishops, with full authority, to inquire into the abuses and corruptions of the Roman court, and to propose the most effectual

method of removing them. It was intended to do as little as possible: still a multitude of enormities were unveiled, an account of which was soon transmitted into Germany, much to the satisfaction of the Protestants there. This investigation, partial as it was, proved the necessity of a reformation in the head as well as the members of the church; and it even pointed out many of the corruptions, against which Luther had remonstrated with the greatest vehemence. It was, however, intended only as a farce, and as such Luther treated it; and to ridicule it more strongly, he caused a caricature to be drawn, in which was represented the pope seated on a high throne, some cardinals about him with foxes' tails, with which they were brushing off the dust on all sides. Luther published, about the same time, "A Confutation of the pretended Grant of Constantine to Sylvester, bishop of Rome; and also some Letters of John Hufs, written from his Prison at Constance, to the Bohemians." On the death of George, duke of Saxony, the succession devolved on his brother Henry, who was zealously attached to the Protestant religion, and who, notwithstanding a clause in his brother's will, by which he bequeathed all his territories to the emperor and the king of the Romans, should Henry make any attempt to introduce innovations, immediately invited Luther and some other Protestant divines to Leipzig. By their aid and advice he quickly overturned the whole system of Popish rites and doctrines, and established the full exercise of the reformed religion, with the universal applause of his subjects, who had long wished for this change. By this revolution, the whole of Saxony was brought within the Protestant pale.

Luther was incessantly employed, till his death, in promoting the cause of which he was the great founder. In the year 1546, he, in company with Melancthon, paid a visit to his own country, which he had not seen before for many years, and he returned in safety; but in a short time after, he was called thither by the earls of Mansfeldt, to compose some differences which had arisen about their boundaries. Though he had not been accustomed to such kind of business, yet he would not refuse the service which he might be able to render by his advice and authority. On this occasion he met with a splendid reception, used his best endeavours to settle the matters in dispute, and sometimes officiated in the church; but the state of his health was so precarious, that it was feared every great effort would prove fatal to him. His last public service was in the church, where he was seized with a violent inflammation in the stomach. His natural intrepidity did not forsake him; and his last conversation with his friends was concerning the happiness reserved for good men in a future life. On the morning of the 12th of February 1546, being awakened from a sound sleep by his disorder, and perceiving his end to be approaching, he commended his spirit into the hands of God, and quietly departed this life at the age of sixty-three. He did not forget his cause even in his dying moments, but admonished those about him to pray to God for the propagation of the gospel; "because," said he, "the council of Trent, which has sat once or twice, and the pope, will devise strange things against it." Immediately after his decease, the body was put into a leaden coffin, and carried with funeral pomp to the church at Eisleben, when Dr. Jonas preached a sermon on the occasion. The earls of Mansfeldt requested that his body might be interred in their territories; but the elector of Saxony insisted upon his being brought back to Wittenburg, which was accordingly done, and he was buried there with greater pomp than had been known to have accompanied the funeral of any private man. Princes, earls, nobles, and students without number, attended

tended the procession, and Melancthon delivered a funeral discourse. He left several children by his wife Catharine de Bore. Innumerable were the calumnies invented by his enemies respecting his death, his principles, and his conduct, which it is needless for us to repeat, as they have been amply refuted by the most respectable historians. The zeal and madness of the Papists against their formidable antagonist, who had shaken to the foundation the pillars of their faith, did not cease with his death. They urged the emperor Charles V., while with his army at Wittenburg, to cause the monument erected to his memory to be demolished, and his bones to be dug up and burnt with every indignity; but the mind of Charles was superior to such childish and malignant acts, and he instantly forbade that any insult should be offered to his tomb, or his remains, upon pain of death. "I have," said the emperor, "nothing farther to do with Luther: he is henceforth subject to another judge, whose jurisdiction it is not lawful for me to usurp. Know, that I make not war with the dead, but with the living, who are still in arms against me." We cannot bring this article to a close, without referring to the testimonies of the learned and the wise respecting the character of Luther, who introduced, not into Germany only, but into the world, a new and most important era, and whose name can never be forgotten while any thing of principle remains that is deserving of remembrance. It must not be overlooked, that the grand and leading doctrine of Lutheranism, and that on which the permanent foundation of the reformed religion was laid, is the right of private judgment in matters of religion. To this, as we have seen, he was at all times ready to devote his talents, his character, and his life; and says the biographer of Leo X., "the great and imperishable merit of the reformer consists in his having demonstrated it by such arguments, as neither the efforts of his adversaries, nor his own subsequent conduct, have been able either to confute or invalidate." In passing judgment upon the characters of men, says Robertson, we ought to try them by the principles and maxims of their own age, and not by those of another: for although virtue and vice are at all times the same, manners and customs are continually varying. Some parts of Luther's behaviour, which to us appear most culpable, gave no disgust to his contemporaries. It was even by some of those qualities, which we are now apt to blame, that he was fitted for accomplishing the great work in which he embarked.

Luther himself was sensible of defects, which he pathetically acknowledges in an address to the reader of his work: "I intreat you," says he "to read my writings with cool consideration, and even with much pity. I wish you to know that when I began the affair of indulgences, I was a monk, and a most mad papist. So intoxicated was I, and drenched in papal dogma, that I would have been most ready at all times to murder, or assist in murdering, any person who should utter a syllable against the pope. I was always earnest in defending doctrines I professed. I went seriously to work, as one who had a horrible dread of the day of judgment, and who from his inmost soul was anxious for salvation. You will find, therefore, in my earlier writings, with how much humility, on many occasions, I gave up considerable points to the pope, which I now detest as blasphemous and abominable in the highest degree. This error my followers may call inconsistency; but you, my pious readers, will have the kindness to make some allowance, on account of the time, and my own inexperience. I stood absolutely alone at first, and certainly was very unlearned, and very unfit to undertake matters of such vast importance. It was by accident, not willingly or by de-

sign, that I fell into those violent disputes. God is my witness."

"Martin Luther, resenting an affront put on his order, began to preach against abuses in the state of religion, and being naturally of a fiery temper, and provoked by opposition, he proceeded even to defy indulgence sellers, and was thence carried, by the heat of dispute, to question the authority of the pope. Still, as he enlarged his views, in order to support these tenets, he discovered faults, or abuse or error in the church of Rome, and finding his opinions greedily hearkened to, he promulgated them by writing, discourse, sermons, conference, and daily increased the number of his disciples. All Saxony, all Germany, all Europe, were in a little time filled with the voice of this daring innovator; and men, roused from that lethargy in which they had so long slept, began to call in question the most ancient and received opinions. The elector of Saxony, favourable to Luther's doctrine, protected him from the violence of the papal jurisdiction: the republic of Zurich even reformed their church according to the new model; many sovereigns of the empire, and the imperial edict itself, shewed a favourable disposition towards it: and Luther, a man naturally inflexible, vehement, and opinionative, was become incapable, either from promises of advancement or terrors of severity, to relinquish a sect of which he himself was the founder, and which brought him a glory superior to all others, the glory of dictating the religious faith and principles of multitudes."

Dr. Campbell, in his lectures on Ecclesiastical History, has rendered our reformer his testimony of respect and gratitude; but as this is conveyed in sentiments and language but little different from the observations of Dr. Robertson, we shall extract the account from the latter rather than the former: "As he was raised up by Providence to be the author of one of the greatest and most interesting revolutions in history, there is not any person, perhaps, whose character had been drawn with such opposite colours. In his own age, one party, struck with horror and inflamed with rage, when they saw with what a daring hand he overturned every thing which they held to be sacred, or valued as beneficial, imputed to him not only all the defects and vices of a man, but the qualities of a demon. The other, warmed with admiration and gratitude, which they thought he merited as the restorer of light and liberty to the Christian church, ascribed to him perfections above the condition of humanity, and viewed all his actions with a veneration, bordering on that which should be paid only to those who are guided by the immediate inspiration of heaven. It is his own conduct, not the undistinguishing censure, or the exaggerated praise of his contemporaries, that ought to regulate the opinions of the present age concerning him. Zeal for what he regarded as truth, undaunted intrepidity to maintain his own system, abilities, both natural and acquired, to defend his principles, and unwearied industry in propagating them, are virtues which shine conspicuously in every part of his behaviour, that even his enemies must allow him to have possessed them in an eminent degree. To these may be added, with equal justice, such purity, and even austerity of manners, as became one who assumed the character of a reformer; such sanctity of life as suited the doctrine which he delivered, and such perfect disinterestedness as affords no slight presumption of his sincerity. Superior to all selfish considerations, a stranger to all the elegancies of life, and despising its pleasures, he left the honours and emoluments of the church to his disciples, remaining satisfied himself in his original state of professor of the university, and pastor of the town of Wittenburg.

with

with the moderate appointments annexed to each. His extraordinary qualities were allayed with no inconsiderable mixture of human frailty, and human passions. These, however, were of a nature, that they cannot be imputed to malevolence or corruption of heart, but seem to have taken their rise from the same source with many of his virtues. Accustomed himself to consider every thing as subordinate to truth, he expected the same deference for it from other men; and, without making any allowances for their timidity or prejudices, he poured forth against such as disappointed him in this particular, a torrent of invective and abuse. Regardless of any distinction of rank or character when his doctrines were attacked, he chastised all his adversaries indiscriminately, with the same rough hand; neither the royal dignity of Henry VIII. nor the eminent learning and abilities of Erasmus, screened them from the same gross abuse with which he treated Tetzel or Eckius. To rouse mankind, when sunk in ignorance and superstition, and to encounter the rage of bigotry armed with power, required the utmost vehemence of zeal, as well as a temper daring to excess. A gentle call would neither have reached, nor have excited those to whom it must have been addressed. A spirit more amiable but less vigorous than Luther's would have shrunk back from dangers which he braved and surmounted. Towards the close of Luther's life, though without any perceptible diminution of his zeal and abilities, the infirmities of his temper increased upon him, so that he grew daily more peevish, more irascible, and more impatient of contradiction. Having lived to be a witness of his own amazing success; to see a great part of Europe embrace his doctrines, and to shake the foundation of papal Rome, before which the mightiest monarchs had trembled, he discovered, on some occasions, symptoms of vanity and self-applause. He must have been, indeed, more than man, if, upon contemplating all that he actually accomplished, he had never felt any sentiment of this kind rising in his breast." There is yet another testimony to the life and labours of this great man that we cannot omit:

"Martin Luther's life," says bishop Atterbury, "was a continual warfare; he was engaged against the united forces of the papal world, and he stood the shock of them bravely, both with courage and success. He was a man certainly of high endowments of mind and great virtues: he had a vast understanding which raised him up to a pitch of learning unknown to the age in which he lived; his knowledge in scripture was admirable, his elocution manly, and his way of reasoning with all the subtilty that these plain truths he delivered would bear, his thoughts were bent always on great designs, and he had a resolution fitted to go through with them, and the assurance of his mind was not to be shaken or surprised, and that *zeugnis* of his (for I know not what else to call it) before the diet of Worms, was such as might have become the days of the apostles. His life was holy, and, when he had leisure for retirement, severe; his virtues active chiefly, and hominical, and not those lazy sullen ones of the cloister. He had no ambition but in the service of God: for other things, neither his enjoyment nor wishes ever went higher than the bare conveniences of living. He was of a temper particularly averse to covetousness, or any base sin, and charitable even to a fault, without respect to his own occasions. If, among this crowd of virtues, a failing crept in, we must remember that an apostle himself had not been irreproachable; if, in the body of his doctrine, one flaw is to be seen, yet the greatest lights of the church, and in the purest times of it, were, we know, not exact in all their opinions. Upon

the whole, we have certainly great reason to break out in the phrase of the prophet and say, "How beautiful, upon the mountains, are the feet of him that bringeth glad tidings." Gibbon, speaking of the effects produced by the exertions of Luther and his contemporaries, says, "The philosopher must own his obligations to these fearless enthusiasts. 1. By their hands the lofty fabric of superstition, from the abuse of indulgences to the intercession of the Virgin, has been levelled with the ground. Myriads of both sexes of the monastic profession were restored to liberty and the labours of social life. 2. The chain of authority was broken which restrains the bigot from thinking as he pleases, and the slave from speaking as he thinks. The popes, fathers, and councils were no longer the supreme and infallible judges of the world; and each Christian was taught to acknowledge no law but the scriptures, no interpreter but his own conscience."

The works of Luther, in the Latin and German languages, were collected and published in an uniform edition, at Jena, in 1556, in four volumes folio; and in 1572 they were printed at Wittenburg, in seven volumes folio. Luther left behind him three sons and a widow. The latter survived him nearly seven years. When the war broke out Catharine wandered about in exile with her children, in difficulties and dangers: she experienced the ingratitude of many, from whom expecting kindnesses, on account of her husband's great merits towards the church, she was frequently disappointed. At length, the plague raging at Wittenburg, and the infection having reached her own house, she removed to Torgau, that she might preserve her children from the disorder. On her way thither the horses in the carriage took fright; to avoid, what she conceived, a greater danger, she leaped into the road, and falling into a pool of water, was dreadfully bruised, and contracted an illness, which in a few weeks terminated her life. Preface to Luther's works: MS. translation of Melchior Adams Life of Luther. Bayle. Robertson. Hume. Gibbon.

Martin Luther, with respect to ecclesiastical music, being himself a lover and judge of the art, was so far from banishing it from the church, that he augmented the occasion for its use. In 1521 he procured the abolition of the ancient mass at Wittenburg. In 1523 Lutheranism was established in Denmark and Sweden; and, in 1525, Saxony, Brunswick, Hesse, Strasburg, and Frankfort. But though he instituted a new liturgy, the ecclesiastical tones still regulated the music of his church at the time of the reformation, and most of the old melodies to the evangelical hymns are composed in some of them.

The Cantata, or anthems and services of the reformed church, in the German language, are, however, as elaborate and florid as the motets to Latin words, used in Italy during the celebration of the mass. But in the hymnologia, and metrical psalmody of this, as well as all other Protestant churches, there seems to have been one common principle, totally inimical to poetry, which is that of destroying all quantity and distinction of syllables, by making them all of the same length.

"These *equal syllables* alone admire,
Though oft the ear the open vowels tire."
Pope.

The modern Methodists, indeed, have introduced a light and ballad-like kind of melody into their tabernacles, which seems as much wanting in reverence and dignity, as the psalmody of other sects in poetry and good taste.

Music, in itself an innocent art, is so far from corrupting the mind, that, with its grave and decorous strains, it

can calm the passions, and render the heart more fit for spiritual and pious purposes; particularly when united with language, and the precepts of religion. It has been said, not improperly, that "Music, considered abstractedly, is in itself a language;" and we may add, that it is more universally understood by mankind in general, whose nerves vibrate in unison with its selected tones, than any other language among all the dialects of the earth. That articulation must be rough and violent indeed, which, without fingering, can easily be comprehended in buildings so vast as some of the Christian churches; in such, it is the *spirit*, not the *letter* of supplication or thanksgiving, which must employ the mind. St. Paul says, "I will sing with the *spirit*, and I will sing with the *understanding* also." As there never was a national religion without music of some kind or other, the dispute concerning that which is most fit for such solemnities, is reduced to one short question. If music be admitted into the service of the church, is that species of it which the most polished part of mankind regard as *good*, or that which they regard as *bad*, the most deserving of such an honour?

That metrical psalmody, in slow notes of equal length, had its origin in Germany, and was brought thence by reformers to other parts of Europe, is demonstrable: for the 128th Psalm, "Beati omnes qui timeant Dominum," had been translated into German verse, in order to be sung in this manner, by John Hufs, in the beginning of the fifteenth century; which translation was afterwards modernized in the same measure, and to the same tune, by Luther. And the same melody which we sing to the 100th psalm, is not only given to the 134th, in all the Lutheran psalm-books, but by Goudimel and Claude le Jeune, in those of the Calvinists; which nearly amounts to a proof that this favourite melody was not produced in England. It is said to have been the opinion of Handel, that Luther himself was its author; but of this we have been able to procure no authentic proof. Tradition, however, gives to this celebrated Heresiarch, as he is called by the Roman Catholics, several of the ancient melodies which are still used in Germany.

LUTHERANISM, in *Ecclesiastical History*, the sentiments of Dr. Martin Luther, and his followers, with regard to religion. See the biographical article **LUTHER**, under which article we have given an account of the life and labours of this eminent reformer; and of the commencement and foundation of that memorable rupture and Revolution in the church, which humbled the grandeur of the lordly pontiffs, and eclipsed so great a part of their glory. See **REFORMATION**.

It has been said indeed by F. Paul, in his History of the Council of Trent, p. 5, and after him by Mr. Hume, in his History of England, vol. i. p. 119, as well as by others, that the Austin friars had been usually employed in preaching indulgences in Saxony; but that Arcemboldi, a Genoese merchant, who was employed by Magdalen, the sister of Leo, to whom he had granted the profits arising from the sale of indulgences in Saxony, to collect the money which should be raised, and his deputies, hoping to gain more by committing this trust to the Dominicans, had bargained with Tetzel; and that Luther was prompted at first to oppose Tetzel and his associates, and to deny indulgences, by a desire of taking revenge for this injury offered to his order. Such was the representation of Bossuet; and other writers, misled by his authority, have circulated a similar opinion. It is proper, therefore, to observe, that the profits arising from indulgences in Saxony and the adjacent countries were granted, not to Magdalen,

the sister of Leo, but to Albert, archbishop of Mentz, who had the sole right of nominating those who published them; moreover, Arcemboldi never had any concern in the publication of indulgences in Saxony; because his district was Flanders and the Upper and Lower Rhine. Besides, the publication of indulgences in Germany was not usually committed to the Augustinians: from the year 1229, that lucrative commission was principally intrusted with the Dominicans; and they had been employed in the same office a short time before the present period: the promulgation of them, at three different periods under Julius II. was granted to the Franciscans, and the guardian of the Franciscans was joined in the trust with Albert on this occasion, though he refused to accept it: and it is remarkable, that for half a century before Luther, viz. from 1450 to 1517, the name of an Austin friar employed in this service occurs but once. To these facts it may be added, that it is far from being probable, that Luther would have been solicitous about obtaining for himself or his order, a commission of this kind, at a time when the preaching of indulgences was become very unpopular; inasmuch that all the princes of Europe, and many bishops, as well as other learned men, abhorred the traffic; and even the Franciscans and Dominicans, towards the conclusion of the fifteenth century, opposed it publicly, both in their discourses and writings: nor was this commission given to the Dominicans in general, but solely to Tetzel. Finally, Luther was never accused of opposing the publication of indulgences from resentment or envy, either in the edicts of the pontiffs of his time, or in the reproaches of his contemporary writers, who defended the cause of Rome from the year 1517 to 1546, and who were far from being sparing of their invectives and calumnies. The reader may find this matter fully stated by Dr. Maclean, the translator of Mosheim's Ecclesiastical History, in vol. iv. p. 31. note (p) 8vo. edit. 1790, and by Dr. Robertson in his Hist. of Ch. V. vol. ii. p. 125. note (*), 8vo. edit.

Lutheranism was formed in the manner stated under the article **LUTHER**; the adherents to which were called Lutherans, from Lutherus, a name which has a Greek turn, and which this great reformer assumed in lieu of his family name *Lotter*, or *Lauter*; it being the custom of those days for men of learning to give themselves Greek names; such were Erasmus, Melancthon, Bacon, &c.

For a full and accurate account of the rise and progress of Lutheranism, the reader may consult Mosheim and Robertson, *ubi supra*. See **PROTESTANTS** and **REFORMATION**.

Lutheranism has undergone some alteration since the time of its founder. Luther rejected the epistle of St. James, as inconsistent with the doctrine of St. Paul, in relation to justification; he also set aside the Apocalypse; both which are now received as canonical in the Lutheran church.

Luther reduced the number of sacraments to two, viz. baptism, and the eucharist; but he believed the impanation, or consubstantiation: that is, that the matter of the bread and wine remain with the body and blood of Christ; and it is in this article, that the main difference between the Lutheran and English churches consists.

Luther maintained the mass to be no sacrifice; he exploded the adoration of the host, auricular confession, meritorious works, indulgences, purgatories, the worship of images, &c. which had been introduced in the corrupt times of the Romish church. He also opposed the doctrine of free-will; maintained predestination; asserted that we are necessitated in all we do; that all our actions done in a state of sin, and even the virtues themselves of heathens, are

crimes; that we are only justified by the imputation of the merits and satisfaction of Christ. He also opposed the fustings in the Romish church, monastical vows, the celibacy of the clergy, &c.

Some authors reckon thirty-nine different sects, which at different times have sprung up among the Lutherans.

LUTHERANS, a sect of Protestants who profess Lutheranism, or adhere to the doctrine and tenets of Luther.

The Lutherans, of all Protestants, are those who differ least from the Romish church; as they affirm, that the body and blood of Christ are materially present in the sacrament of the Lord's supper, though in an incomprehensible manner; and likewise represent some religious rites and institutions, as the use of images in churches, the distinguishing vestments of the clergy, the private confession of sins, the use of wafers in the administration of the Lord's supper, the form of exorcism in the celebration of baptism, and other ceremonies of the like nature, as tolerable, and some of them as useful. The Lutherans maintain, with regard to the divine decrees, that they respect the salvation or misery of men, in consequence of a previous knowledge of their sentiments and characters, and not as free and unconditional, and as founded on the mere will of God. Towards the close of the last century, the Lutherans began to entertain a greater liberality of sentiment than they had before adopted; though in many places they persevered longer in severe and despotic principles than other Protestant churches. Their public teachers now enjoy an unbounded liberty of dissenting from the decisions of those symbols or creed, which were once deemed almost infallible rules of faith and practice, and of declaring their dissent in the manner they judge the most expedient. Mosheim attributes this change in their sentiments to the maxim, which they generally adopted, that Christians were accountable to God alone for their religious opinions; and that no individual could be justly punished by the magistrate for his erroneous opinions, while he conducted himself like a virtuous and obedient subject, and made no attempts to disturb the peace and order of civil society. *Ecl. Hist.* vol. iv. p. 440. Eng. ed. 8vo.

LUTHERN, from the French *lucarne*, of the Latin *lucerna*, *light*, or *lantern*, a kind of window over the cornice, in the roof of a building; standing perpendicularly over the naked of the wall; and serving to illuminate the upper story.

The French architects distinguish these into various kinds, according to their various forms; as *square*, *semicircular*, *bulls' eyes*, *flat arches*, *Flemish lutherns*, &c.

LUTHIER, *Fr.* implies not only a lute maker, but a maker of all stringed and bowed instruments.

LUTI, **BENEDETTO**, in *Biography*, a Florentine, was the disciple of Gabbiani, and from him went to Rome, to put himself under the direction of Ciro Ferri; but being disappointed by his death, formed a style of his own, the result of various imitations; select in design, amene and lucid in colour, well contrasted by masses of light and shade, and harmonious to the eye.

He painted not without merit in fresco, and with greater merit in oil. "Cain flying from his murdered Brother," has something of the sublimity and the pathos that strike in the Pietro Martyre of Titian, and his Psyche in the gallery of the Capitol, breathing refinement of taste and elegance. He died in 1724, at the age of 58. Fufen's Pilkington.

LUTKENBURG, in *Geography*, a town of the duchy of Holstein; 30 miles N. of Lubeck.

LUTOMIRSK, a town of the duchy of Warsaw; 18 miles S.S.E. of Lencicz.

LUTON, a considerable market-town and parish in the

hundred of Flitt, Bedfordshire, England, is situated among some hills on the banks of the river Lea, three miles from Dunstable, and 31 from London. The town is long and irregular, shaped something like the Roman Y, the angles branching off from the market-house, which is an extensive building. The population of the parish, according to the return in the year 1801, was 3095, inhabiting 612 houses, which are but indifferently built. The only structure in the town deserving attention is the church, which consists of a choir, a nave and two aisles, supported by ten pointed arches, two transepts, and a handsome embattled tower at the west end, chequered with flint and free-stone; at the corners are hexangular turrets, similar to that at Dunstable. The arch of the west door is ornamented with mouldings of various flowers, &c. Within the church is a singular piece of ancient architecture, an octagonal stone font, inclosed in a lofty wooden frame of pointed arches, terminated with elegant tabernacle work. The consecrated water, during the prevalence of the Roman ceremonies, was kept in a large basin at the top, whence it was let down by the priest, through a pipe into the font. On the inside of the roof a vine is represented, guarded by a lamb from the assaults of a dragon: emblematical of the defence which baptism affords to the church from the attempts of the devil. On the north side of the choir is an elegant chapel, founded by John lord Wenlock, who bore a distinguished part in the contest between the houses of York and Lancaster. The principal manufacture carried on in Luton is that of straw hats: a weekly market, noted for its abundant supply of corn, is held on Mondays; it is of great antiquity, being mentioned in the Domesday Survey, where the tolls are valued at 100s. *per annum*: and here are two annual fairs. John Pomfret, the poet, was a native of this town: his father was first curate and then vicar of the parish.

About three miles from the town, on an elevated situation at the border of the Bedfordshire downs, in the midst of a well wooded park, stands Luton-Hoo house, the seat of the marquis of Bute. The old park, which consisted of about 300 acres, inclosed by sir Robert Napier, was enlarged to 1200, by the late earl of Bute, and now contains about 1500 acres. The mansion was in a great measure rebuilt by the late earl, who employed Mr. Adam the architect. The principal rooms, particularly the library, drawing-room, and saloon, are on a magnificent scale. The library, which is 146 feet in length, is esteemed but little inferior to that of Blenheim. The collection of pictures is very large and valuable, chiefly of the Italian and Flemish schools. The chapel is fitted up with carving in wood, which was originally executed for sir Thomas Pope at Tottenhanger, Herts. in 1548, and removed to Luton in perfect preservation by sir Robert Napier. In the adjoining wood is a portico, a beautiful piece of brick building, designed for a mansion intended to have been built by lord Wenlock, but which was never completed: and in the park is a stone tower of great antiquity. *Beauties of England and Wales*, vol. i. Lysons's *Magna Britannia*, vol. i.

LUTRA, in *Zoology*, a species of *Muscula*. See *MUSCULA Lutra*, and *OTTER*.

LUIRY, in *Geography*, a pleasant little town of Switzerland, in a district of the Pays de Vaud between Lausanne and Vevey, called "La Vaux," on the N. coast of the lake of Geneva; three miles E. of Lausanne.

LUTTENBERG, a town of the duchy of Stiria, on the river Sava; 12 miles E. of Pettau. N. lat. 46° 35'. E. long. 16° 8'.

LUTTER, a town of Westphalia, in the duchy of Brunswick; 11 miles N.W. of Goslar.

LUTTER-

LUTTERBERG, a town of Westphalia, in the principality of Grubenhagen, formerly a county; 15 miles S. of Göttinge.

LUTTERHAUSEN, a town of the duchy of Holstein; eight miles from Hamburgh.

LUTTERLOCK, a township of America, in Orleans county, Vermont, N. of Craftsborough.

LUTTERWORTH, the only market town in the hundred of Guthlaxton, Leicestershire, England, is situated on the bank of the river Swift; about two miles from the Watling-street road, 13 miles from Leicester, and 83 from London. Leland describes this "towne as scant half so bigge as Loughborow; but in it there is an hospital of the foundation of two or three of the Verdunes, that were lords of ancient tyme of the town." This hospital was founded, in the reign of king John, by Roife de Verdon and Nicholas her son, for a priest and six poor men, and to "keep hospitallity for poor men travelling that way." The parish church of Lutterworth is a spacious structure, with a nave, two aisles, a chancel, and a tower with four turrets. The chancel, which is separated from the nave by a beautiful screen, is supposed by Burton to have been built by lord Ferrers of Groby, as his arms are cut on the outside over the great window. By a storm, in the year 1703, the spire, which was 50 feet higher than the present turrets, was blown down, and, falling on the roof of the church, did great damage to the body, pews, &c. About the year 1740, the whole was repaired, a pavement of chequered stone laid, and all the interior made new, except the pulpit, which is of thick oak planks, of an hexagonal shape, and has a seam of carved work in the joints; this pulpit is preserved with great veneration, in memory of the distinguished reformer, John Wickliffe, who was rector of this parish, and died suddenly while hearing mass December 31st, 1387. The chair in which he breathed his last is also preserved with great care; as is likewise another relic used by him, the communion cloth of purple velvet trimmed with gold. His body was buried in this church; but his doctrines having been condemned, his remains were taken up and burned, by order of the council of Sienna, in 1428, and his ashes cast into the river. His portrait, by S. Fielding, hangs over the gallery at the west end of the church. A meeting-house for dissenters was built here in 1777, and is numerously attended. Here are also a school-house and alms-house, built by the bequest of Mr. Edward Sherrier. Among other benefactions to this town, Mr. Richard Elkington, by his will, dated May 20th, 1697, left in trust to the mayor, bailiff, and burgesses of Leicester 50*l.* to be lent in sums of 1*l.* each to five tradesmen of Lutterworth for one year at five *per cent.*; the interest to be distributed among certain poor persons. In the return to the population act in 1801, this town was stated to contain 277 houses and 1652 inhabitants. The cotton manufacture is carried on here to considerable extent; and some large buildings have been lately erected as factories and workshops. Many hands are also employed in making stockings. A weekly market is held on Thursdays, granted, with an annual fair, by king Henry V. in the second year of his reign; three other fairs have since been obtained.

About a mile to the east of Lutterworth is Milterton Hall, the seat of Jacob Henry Franks, esq. who possesses a collection of pictures. Nichols's History of Leicestershire. Beauties of England and Wales, vol. ix.

LUTUM, in *Botany*, a name given by the ancient Roman authors to a plant since called *luteola*, or dyer's-weed, and by authors of later date *carniola*, and *cymene*. It is used at this time to dye things yellow, and was so by the

ancient Greeks, who expressly mention the dyeing woollen cloth with it. The Roman courtizans had also a way of dyeing their hair yellow with it. See *RESEDA*.

LUTUM *Supientia* is the hermetical seal; made by melting the end of a glass vessel by a lamp, and twirling it up with a pair of pliers.

LUTZELSTEIN, in *Geography*. See *La Platte Pierre*.

LÜTZEN, a town of Saxony, in the territory of Merseburg, with a citadel. Near this town was fought a bloody battle in 1632, between the Imperialists and Swedes, in which the latter lost their king Gustavus Adolphus; nine miles E.S.E. of Merseburg. N. lat. 51 16'. E. long. 12 8'.

LUVINO, a town of Italy, in the department of the Verbano, on the E. bank of the lake Maggiore; 20 miles N.W. of Como.

LUVINO, *Valley of*, one of the five districts into which the county of Bormio is divided. (See *BORMIO*.) The inhabitants of the Luvino possessed certain privileges, particularly the power of judging civil causes within a certain value; but they did not appoint any of the magistrates, who were all chosen from the other four districts.

LUVIO, a town of Sweden, in the government of Abo; nine miles S.S.W. of Biorneborg.

LUXATION, or **DISLOCATION**, in *Surgery*, denotes any case where the articular extremities of bones abandon their natural relations, whether the head of a bone escapes from a cavity destined for its reception, or whether the surfaces of the joint cease to correspond properly one to the other. A luxation is termed *complete*, when the surfaces of the joint are totally separated; *incomplete*, when they remain partially in contact, though in a state of displacement, with respect to each other. Like fractures, dislocations are also divided into *simple* and *compound*; simple, when there is no external wound communicating with the joint; compound, when the case is conjoined with such an accident.

Other general differences of luxations depend upon the articulation in which they take place; the direction in which the bone is displaced; the length of time the accident has continued; and the cause that has produced it.

The greater the extent and variety of motion of joints, the more subject they are in general to be dislocated. Thus, the orbicular articulations, such as that of the humerus with the scapula, are these in which luxations are most frequent. In the ginglymoidal articulations, on the contrary, which admit only of motion in two opposite directions, the accident is far less common; and in such joints as only allow a slight yielding motion of the bones on each other, a dislocation still more rarely occurs. The frequency of luxation, however, in the orbicular articulations, and the comparative unfrequency of them in the ginglymoidal, as Boyer rightly observes, may be explained from many circumstances, independent of the quantity and variety of motion which such joints admit of. In the ginglymoidal, the bony surfaces, which come into contact, and are adapted to one another, are of considerable extent; the ligaments which bind them together are very numerous and strong; and the muscles are so arranged, as to have a share in strengthening such articulations.

We have mentioned, that luxations are distinguished into *complete* and *incomplete*, the latter term being used, when the surfaces of the joint are yet partially in contact, though displaced and not exactly corresponding. Incomplete luxations only happen in the ginglymoidal articulations, as those of the foot, the knee, and the elbow. In these joints, indeed, the dislocation is almost always incomplete; as it could

LUXATION.

only be made complete by the operation of a vast force. With respect to the orbicular joints, it is very different, as few of them are subject to any dislocation, that is not complete. If the head of the humerus, or thigh-bone, is forced on the cartilaginous brim, surrounding the cavity defined for its reception, the round slippery ball only touches the part on which it rests by a few points, and, therefore, either re-enters its natural socket again, or slips entirely from it; in the latter event, of course the luxation is complete.

But as M. Boyer has noticed, there are some articulations which, though truly orbicular, are yet liable to incomplete luxations. For instance, the head of the astragalus may be so displaced, as only to abandon, in a partial manner, the cavity in the posterior surface of the os naviculare. However, in this example, the orbicular ligament is tight, very strong, and the motion inconsiderable. Lastly, it may be observed, with regard to the extent of dislocations, that when the head of a bone is entirely thrown out of the cavity, in which it is naturally placed, it may be forced to a greater or less distance between the interstices of the muscles.

On the subject of the different directions, in which a bone may be displaced, we have to state, that, in the round articulations, it may be luxated in the direction of all the radii, which pass from the centre of the circle formed by the circumference of the articular cavity. In fact, there is not a point of the edge of the glenoid cavity where the humerus may not escape. However, owing to particular circumstances of conformation, a luxation mostly takes place in certain directions, well ascertained by experience, so that the varieties of dislocations, distinguished by the course of the displaced bone, are, as Boyer well explains, much less numerous than might at first be supposed. The terms *upwards, downwards, forwards, backwards, inwards, and outwards*, are frequently applied to luxations, as denoting the direction in which the head of a bone is displaced. Ginglymoid joints are generally susceptible of being dislocated only in the direction of two lines, namely, a transverse one, and one extending from the front to the back of the articulation.

The length of time a dislocation has existed makes a difference of the highest importance, the difficulty of cure increasing in proportion to the time the accident has been left unreduced; and, indeed, after a certain time, the reduction becomes impracticable.

The soft parts and the bone itself have acquired a certain position, and the ligaments and muscles surrounding the diseased joint become stiff, and yield with difficulty to the efforts made to reduce the bone. If a certain number of days have elapsed, the laceration in the ligaments may have become so far closed as to render the reduction impossible. Lastly, the head of the bone may have become firmly adherent to the parts, amongst which it has been forced.

Luxations, in general, may be complicated with a greater or less degree of contusion, with a wound or fracture, with a rupture of a blood-vessel and consequent effusion of blood in the cellular substance, with contusion of an important nerve, and a paralysis of the organs to which it is distributed, &c.

The following general account of the causes, symptoms, prognosis, and treatment of luxations, is chiefly from Boyer's lectures on the diseases of the bones.

The causes are divided into external and internal; both are predisposing or occasional.

The predisposition to luxation may depend on circumstances natural or accidental. The natural are, the joint admitting of great latitude of motion, the small extent of

surfaces by which the bones are in contact, the laxity and small number of the ligaments uniting them, the weakness of one side of an articulation arising, for instance, from a great notch on one side, as is observed at the interior and inferior part of the acetabulum, disease, such as a paralysis of the muscles, which surround an articulation, and a weakness and relaxation of its ligaments, may also occasion a predisposition to dislocations. In a paralysis of the deltoid muscle, the weight of the arm alone has been known to produce an elongation and gradual relaxation of the capsular ligament of the shoulder joint, and to remove the head of the humerus two or three inches from the glenoid cavity of the scapula. Boyer has observed in a child that laboured under an atrophy of the muscles of the arm, an empty space of nearly an inch between the head of the bone and the surface of the glenoid cavity, which could be distinctly felt through the emaciated deltoid muscle.

Sometimes the relaxation of the ligaments appears without any evident cause, and gives such a disposition to luxations, that they take place from the slightest causes; such was the case of a woman who could not yawn even moderately, without luxating the lower jaw. It may not be amiss to observe that these luxations, depending on excessive looseness of the ligaments, are, by reason of such looseness, in general very easily reduced. A diseased state of joints may also dispose to luxations, by destroying the ligaments and articular surfaces. What surgeon of any experience at all has not frequently seen examples in which the head of the thigh-bone has been dislocated, in consequence of disease in the hip? Even the knee, which is a ginglymoidal joint, sometimes becomes partially luxated in cases of white swelling.

In order that external violence, a blow, a fall, or even the action of the muscles, produce luxation in a ball and socket articulation, the axis of the bone must be placed in a direction, more or less oblique, with respect to the surface with which it is articulated. If, for example, the os humeri hangs exactly along the side of the body, or perpendicularly with respect to the glenoid cavity of the scapula, no force can produce a luxation. If a person falls on the elbow, while the fore-arm is in this position, the head of the humerus will be forced against the cavity formed for its reception; but if the arm is lifted more or less from the body, the axis of the humerus will fall obliquely on the surface of the glenoid cavity, and the escape of the head of the bone from such cavity will be facilitated. This tendency to a dislocation will be increased in proportion as the angle formed by the axis of the bone with the surface of the glenoid cavity deviates from a right angle. In the ginglymoidal articulations luxations may be caused by a fall, or other kinds of external violence, and they are mostly incomplete. In the orbicular joints the action of the muscles has constantly a share in the production of the accident. Thus, for instance, if a person falls on the elbow, whilst the arm is raised from the body, and carried directly outwards, the shock which this part receives will certainly tend very much to force the head of the humerus out of the glenoid cavity on the lower and internal side; but the action of the pectoralis major, latissimus dorsi, and teres major, contributes also very much to throw the bone out of its place. In fact the elbow, resting on the ground, becomes the fulcrum, or centre of motion of the humerus; in this state, we obey a mechanical instinct, which leads us suddenly to bring the arm close to the body, and as the resistance made by the ground prevents this, the violent and instantaneous contraction of the pectoralis major, latissimus dorsi, and teres major, draws downwards and inwards the head of the humerus; the luxation being

LUXATION.

being thus partly the effect of the fall, and partly the effect of such muscular action. Whatever may be the manner in which the causes act, luxations are always accompanied with more or less laceration of the ligaments, and injury of the other soft parts about the joint; and in the orbicular articulations, like those of the shoulder and hip, the capsular ligaments are always torn.

With respect to the general symptoms of luxations we need not dwell much upon pain and inability of moving the limb, as, at most, they are only equivocal, and common to dislocations, fractures, and simple bruises. They are not, however, to be entirely overlooked, but still in forming a diagnosis we should endeavour to find it on the existence of symptoms manifest to the senses, such as an elongation or shortening of the limb; a change in its shape and direction; and lastly, the absolute impossibility of performing certain motions.

A luxation cannot possibly exist, unless the affected limb is either lengthened, as happens in the lower extremity, when the head of the femur passes out of the acetabulum, in the direction downwards and inwards, and rests on the foramen ovale; or shortened, as takes place when the same bone is luxated upwards and backwards, and has its head thrown towards the external depression in the ilium. But it is to be remarked, that the shortening and elongation are rarely produced, except by luxations of orbicular joints. However, the absence of these symptoms in dislocations of the ginglymoidal articulations is amply compensated by the superficial situation of the bone; a circumstance which renders it easy to ascertain their relative positions.

The direction of the bone is changed, for the luxated end cannot leave its natural place, without the other being thrown into a contrary direction. Thus, in the luxation of the humerus downwards and inwards, the position of the arm is obliquely downwards and outwards, instead of being straight along the side. This mode of judging of the occurrence of a dislocation by the change in the direction of the limb, is much easier in recent cases, than in those which have continued for a considerable time.

As the situation and direction of a dislocated bone are altered, it necessarily follows that some muscles must be preternaturally relaxed, while others are overstretched and strained, as may be seen with respect to the deltoid muscle, in cases of luxations of the humerus, which are the most frequent of all. This unequal tension and relaxation of muscles may also afford some assistance in forming the diagnosis.

Time seems, however, something to remove, in a great measure, the alteration produced in the contour of a limb, by certain luxations; and it is observed that in old dislocations of the humerus, the fulness of the shoulder, just below the acromion, is in some degree restored.

In these alterations of the natural shape of the limbs, we are to comprehend the changed relations of the eminences of a joint with respect to each other; the existence of projections in places, where there ought to be depressions; and of depressions where there ought to be eminences. Thus, in the luxation of the humerus inwards and downwards, a hard tumour caused by the head of the bone itself, may be distinctly felt in the hollow of the axilla, while an unnatural depression may be perceived just under the acromion.

Our limbs, even when fractured, as Boyer has observed, may be made to perform several motions, and may be put into various attitudes. In a case of a broken thigh, the surgeon (not, in truth, without causing severe pain,) may, by taking hold of the leg, move it round in a circular direction, and may point the foot inwards and outwards.

But in luxations of the thigh, such motions are altogether impossible, before the bone is reduced.

By a consideration of all these symptoms, dislocations may always be detected. When the case is not ascertained within a moderate time, either through negligence or ignorance, it is a serious affair for the patient; because the inability of using the limb is imputed to the contusion, and the treatment is regulated accordingly; the bone, after a time, becomes incapable of reduction, and the lameness and deformity are then irremediable. Such surgeons as are grossly deficient in anatomical knowledge, are the most liable to deliver wrong opinions concerning dislocations; for, not being able to judge of the due relative distances which ought to exist between certain processes of the bones, they are not at all qualified to decide whether many cases are mere contusions, or whether they are fractures or dislocations.

On the subject of prognosis in cases of dislocation, it is remarked that luxations of the orbicular joints are much less dangerous than those of the ginglymoidal articulations. As the action of the muscles has a great share in producing the first description of cases, there is less violence done to the external parts, and the soft parts are less lacerated.

In all cases the extent of the evil is in proportion to the largeness of the surfaces of the joint, the number and strength of the surrounding muscles, and the thickness and number of the ligaments. Hence, luxations of the foot and knee are more dangerous than those of the elbow and wrist; the former require a much greater degree of external violence to produce them, and consequently the soft parts are more injured.

Luxations of the orbicular joints are more difficult of reduction than those of the ginglymoidal articulations, and dislocations of the hip are more troublesome to reduce than luxations of the shoulder. These circumstances are explicable by the power and action of the muscles, in resisting the endeavours of the surgeon to bring the head of the bone into its place again.

But, perhaps, the thing which, of all others, tends most to increase the danger of a dislocation, is the accident being, what is termed *compound*, that is, attended with an external wound, communicating with the cavity of the luxated joint. Many such cases require immediate amputation. The propriety of the operation depends, however, in a great measure on the extent of injury done to the soft parts. When these have not been largely lacerated, torn, and contused, the surgeon should endeavour to save the limb. Even the hazard of a compound dislocation very much depends on the kind of joint affected. Such injuries of the articulations of the fingers or toes cannot be compared, in point of danger, with similar accidents intersting the ankle, the knee, or the elbow.

Luxations arising from disease of a joint, cannot in general be reduced and cured like dislocations from external violence; for the ligaments and articular surfaces are, in fact, always more or less destroyed. This observation, however, is not to be extended to luxations, induced by a mere looseness of the ligaments. These cases indeed are very subject to recur; but they can easily be reduced. Many dislocations of the jaw are connected with a lax state of the ligaments, and afford an illustration of the preceding remark.

Lastly, the danger of dislocations in general is much influenced by the degree of contusion present, and by the injury done to blood-vessels, or large nerves. The latter violence sometimes occasions a paralysis of the muscles, to which the injured nerves send its filaments. Boyer has seen a paralysis of the deltoid muscle brought on by a violent contusion

tusion of the circumflex nerve, in a luxation of the humerus downwards and inwards.

We have now to consider the general treatment of luxations.

To reduce the dislocated bone, keep it in its place, and prevent or remove the symptoms with which the luxation may be complicated, form the three indications which are to be fulfilled in the treatment of luxations. The reduction is accomplished, as in cases of fracture, by three means, opposite in their action, but tending to the same end, *viz.* extension, counter-extension, and coaptation.

In the article FRACTURE we have expatiated a good deal on relaxing the muscles connected with the broken bone, in order to facilitate the reduction of the fracture. This great principle, which was so much and so justly urged by Mr. Pott, holds equally good in cases of dislocation. From the action of the muscles principally arise all the trouble and difficulty which attend the reduction of luxated joints. The mere bones, composing the articulations, or the mere connecting ligaments, would in general afford very little opposition. It is the muscles that chiefly oppose the reduction, and their resistance must either be eluded or overcome; terms, says Mr. Pott, of very different import, and which every practitioner ought to be well apprized of. We scarcely need add, that this eminent surgeon was a strong advocate for relaxing the muscles belonging to the dislocated joint, at the time of attempting to reduce the bone. Now, although this precept is, generally speaking, most excellent as far as it is practicable; we are not to run away with the idea that things are precisely as Mr. Pott has represented them to be, in his general remarks on fractures and dislocation. No surgeon, of the present time, is so absurd as to imagine that merely bending the elbow, or the knee, will relax all the muscles which have the power of resisting the reduction of a dislocated shoulder or hip. Neither will the most advantageous position for extension always allow the posture to be entirely regulated with a view towards the relaxation of the muscles. While, however, we profess these sentiments, we feel a thorough conviction that attending to the relaxation of such muscles as have the greatest power of opposing the reduction of a dislocation, is an unobjectionable maxim, as far as it can be received in actual practice, consistently with some other equally important objects. When Mr. Pott wrote so strenuously in favour of relaxing the muscles, or, as we should rather say, of bending joints, in cases of dislocation, it was also necessary for him to lay much stress on the advantage of applying the extension to the end of the dislocated bone itself; because, were it applied in a better situation, the bent position would become inadmissible. The reason which is assigned for this practice, however, is, as might be expected, most weak. Mr. Pott talks a great deal about the *dilatibility*, or *distensible power* of the ligaments, and their capacity of giving way when stretched or pulled, much more, we think, than facts justify, since it is the general nature of ligaments, we mean such as actually hold the bones together, to be very strong and unyielding. The capsular ligaments, we think, are generally to be regarded rather as bags for the synovia, than as a means of strengthening the articulations. The yielding nature of such ligaments, therefore, can have little to do with the subject of dislocations. Now it appears to us that Mr. Pott was anxious to make the ligaments appear more elastic than they really are, in order that he might represent all the extending force applied to the bone below the dislocated one, as being lost in the intervening unluxated articulation. Even were the ligaments of the knee, for instance, to yield in the manner

insinuated by Pott, when the extension is applied to the lower part of the leg, the extending force would still not be lost, but would operate with full effect on the thigh. Where is it lost? The very circumstance of the ligaments being on the stretch, proves that the force operates on them, and they being attached to the os femoris, this bone cannot fail to receive the extension in a degree precisely equal to that with which the ligaments themselves receive it. It is extraordinary that reasoning so absurd should have imposed upon the generality of surgeons in this country; especially as on the continent, its fallacy has long since been exposed in the writings of Fabre, Dupony, Desault, Boyer, and Richerand. The doctrine of Pott is the most ancient; but the antiquity of any practice should cease to be a reason for a perseverance in it, the moment the principles, on which it is founded, are proved to be erroneous.

We differ then from Pott, and believe with the most consummate surgeons on the continent, that the extending force should be applied, not on the luxated bone, but on that with which it is articulated, and as far as possible from it.

All the ancient authors, as Boyer remarks, advised applying the extending force on the luxated bone, for instance applying it above the knee in luxations of the thigh-bone, and above the elbow in those of the humerus. Many of the moderns have followed their instructions; and this mode is found recommended by J. L. Petit and Duverney in their treatises on the diseases of the bones. Two members of the Academy of Surgery in France, Fabre and Dupony, saw the inconvenience of this practice, and substituted for it a mode of treatment now generally adopted on the continent. Their practice, which consists in applying the extending force to the bone that articulates with the luxated one, has two most important advantages; first, the muscles which surround the luxated bone are not compressed nor stimulated to spasmodic contractions, which would prevent the reduction, not only by opposing a force superior to that employed for the purpose of reduction, but also by retaining the head of the bone engaged in the interstices of the contracted muscles. Secondly, the extending force is much more considerable than it is in the other method, for, as Dupony has observed, by elongating thus the arm of the lever, we acquire a degree of power which the difficulties presented in a great number of cases force us to have recourse to. It is true, says Boyer, an apprehension has prevailed that the extending force applied at a distance from the luxated bone, would lose in the articulations of the limb a part of its effect. Thus it has been alleged, that a part of the extending force applied at the wrist, in a luxation of the humerus, is employed in elongating the ligaments of the elbow joint. But this objection is ill founded; all the muscles which go from the humerus to the bones of the fore-arm, by strengthening the elbow, make it answer as a continued lever, along which the force is communicated without any loss.

Force, applied by the hands of intelligent and strong assistants, is generally considered preferable to any mechanical means in the reduction of dislocations. The number of assistants may be increased at will, and force proportioned to the resistance that is experienced. Should there not be room for a sufficient number to take hold of the limb, they may make the extension by means of a napkin, or sheet, folded longitudinally and tied on the limb. It is said that the force employed can be better judged of when the extension is made by a certain number of assistants, than when a multiplied pulley is used, which may act with such force, without our being aware that the muscles, ligaments, and

and even the skin which covers the articulation, may be lacerated, and the most direful sufferings occasioned.

Although the writer of this article fully assents to the general superiority of making the extension by the assistants, he cannot refrain from expressing a favourable opinion of the convenience and efficiency of a pulley, in cases where intelligent assistants are not at hand, and where much force is required for the reduction, as, for instance, when the thigh-bone, or humerus, has been out of its place some time; or when the patient is very muscular and strong. At the same time, the dangerous consequences which may happen, when a rough, unskilful, or impatient practitioner dares to employ a pulley, cannot be too deeply impressed upon a surgeon's mind. Whether extension is made in the ordinary way, or with a pulley, it should be made with moderation, as the muscles are more sure of being safely overcome by length of resistance than by the exertion of violence.

It is impossible to assign the precise degree of force to be employed; it is to be varied and proportioned, according to the strength of the patient, and the number and force of the muscles surrounding the articulation. It has been said, that, in reducing a luxation, there is occasion for more address than force; it would be true, observes Boyer, to say, that the union of both is necessary. Often six assistants accomplish that which three cannot do, and nine or ten perform that which cannot be done by six.

With regard to the direction in which the extension should be made, Boyer recommends it to be at first the same as that which the luxation has given the dislocated bone. Suppose the head of the humerus to be luxated inward, and forced into the fossa subscapularis, between the subscapularis muscle and the scapula: in this case, the elbow is not only moved out from the trunk, but even carried backwards. Now, if we were to commence the reduction, by pulling in the natural direction of the humerus, that is, directly outwards, the head of the bone would be pressed against the fossa subscapularis, it would not easily slide along, the force would be spent in pushing the scapula backwards, and the irritation would excite the contraction of the muscles situated near the luxated head of the bone.

Extension, then, is generally to be made at first in the direction which the luxated bone has taken; but in proportion as the muscles become elongated, and yield to the force acting on them, the bone is to be gradually brought back into its natural position. In this manner the head of the bone is disengaged from the parts in which it has been placed, and is brought back to the cavity which it has left, by making it describe the same course that it took in making its escape.

We are now to consider what is termed *counter-extension*.

As Boyer has justly remarked, the best directed extension will be useless, if the bone with which the luxated one has been articulated, is not kept motionless by counter-extension, a force equal to the other, but made in a contrary direction. The counter-extending power, applied to the luxated bone itself, would be attended, in almost every case, with the double inconvenience of producing a spasmodic contraction of the muscles, and preventing the elongation of them necessary for reduction. Let us suppose, says Boyer, that in a luxation of the thigh, the counter-extending bandage were in the fold of the groin of the affected side, the consequence would be, that the triceps and gracilis, which are in a state of tension between the pelvis and thigh, would be pushed upwards, and, consequently, shortened, when their elongation is absolutely necessary. Besides, the counter-extension made on them would also increase their contraction. The counter-extending force ought, therefore,

to be applied immediately above the luxated bone. Sometimes the counter-extension is made by assistants, who take hold of the bandage necessary for the purpose; sometimes it is executed by fastening the bandage to a fixed point. The latter mode, when practicable, is to be preferred. The counter-extension should always be made in a perpendicular direction with respect to the surface of the luxated joint. In a luxation of the elbow, for instance, the counter-extension should be made in a line parallel to the os humeri; and in a dislocation of the thigh-bone, the counter-extension, applied to the pelvis, should be made perpendicularly to the surface of the acetabulum. The same rule is to be observed with regard to the shoulder in luxations of the humerus.

In general, when the extension is sufficient, coaptation is easily performed. In a luxation of the humerus, as the head of the bone is disengaged, and the assistants have brought the bone into its natural direction, the surgeon is to seize the opportunity, and with one hand press on the superior and inner part of the arm, whilst, at the same time, he supports the elbow with the other, and thus conducts the head of the bone into the glenoid cavity.

It is an excellent maxim, whenever practicable, to use a dislocated bone as a sort of lever, in making the reduction. Thus, after the head of the humerus has been disengaged by the extension, if, while pressure is made at the upper and inner part of the arm, the elbow is depressed, the head of the bone moves upwards in proportion towards the glenoid cavity of the scapula. The recollection of this principle will materially aid in reducing dislocations of the jaw, thigh bone, &c. Common sense points out, in almost every case, how and where the fulcrum should be made.

Luxations of ginglymoidal articulations being seldom complete, the extension and counter-extension are generally made, in such instances, only with a view of diminishing the friction of the surfaces of the joint, necessarily occasioned by the opposite motions given them, with a view of replacing them in their natural situation.

When extraordinary difficulty is encountered in reducing a dislocation, the surgeon should endeavour to ascertain the cause. Sometimes want of success is owing to the insufficiency of the means employed, in which circumstance, we must either increase the extending power, or diminish the muscular force of the patient.

The latter object may be fulfilled in various ways. Change of posture often produces the effect. In Boyer's work instances are mentioned in which patients, while seated on a chair, and supporting themselves with their feet against the ground, could not have their luxations reduced with the greatest efforts; and yet afterwards had their dislocations reduced with unexpected facility, on being laid horizontally on a long fixed table, where their muscles were deprived of a centre of motion. In general, however, the benefits of posture may, with more reason, be imputed to its relaxing the most powerful muscles opposing the endeavours of the surgeon.

When every attempt, conducted on the foregoing principles, proves ineffectual, the patient is to be warmly and repeatedly bled, be put into the warm bath, and confined to a very low diet. As soon as he appears to be considerably weakened by this plan, the dislocation, which was previously irreducible, may frequently be reduced with the utmost ease. We do not coincide with Boyer, when he advises us to use twenty-four hours in lowering the patient, before renewing the attempts at reduction. On the contrary, to truly are we convinced of the delicacy of reduction, always proceeding from delay, that we earnestly recommend the efforts to reduce the bone to be renewed immediately after the patient

has been weakened by the first copious bleeding, and to be tried again as soon as he has been a certain time in the bath. The faintness and debility following such means, afford the most favourable opportunity for reducing a dislocation. The state of intoxication, induced by spirits or opium, is also well known to facilitate the reduction of luxated bones, by incapacitating the muscles to make resistance, and putting them into a condition in which they yield and become elongated by a very moderate force. Thus Boyer, by himself, and at the first attempt, reduced a luxation of the arm of an intoxicated postillion, while the assistants were preparing the apparatus for the reduction. The plan of purposely intoxicating patients, whose dislocations cannot be reduced by ordinary means, has even received the recommendation of some surgical authors.

But, perhaps, of all the plans proposed for overcoming the resistance of the muscles to the reduction of dislocations, fatiguing those organs by long continued unremitting extension is, when combined with due attention to the choice of such a position as will relax the most powerful ones, the most effectual that can be adopted. The strongest muscles may always be overcome by keeping up, for a certain time, even a very moderate degree of extension. The thing is not to remit or discontinue for a moment the operation of the extending power. This principle is said to have been first applied to practice by Lebat, who, in a case where the levatores of the lower jaw were spasmodically contracted, in a dislocation of that bone, and would not allow the part to be brought down, introduced a small stick between the teeth, and making use of it as a lever, opposed the action of the muscles until they were incapable of further resistance, and the reduction was accomplished. M. David is also stated to have derived similar advantages from the same practice, in luxations of the thigh and arm.

When luxations have been left unreduced several days, the reduction frequently becomes exceedingly difficult, and sometimes quite impracticable. The lacerated opening in the capsular ligament, after a time, becomes closed, and thus a material impediment to the reduction is occasioned. When a dislocation has existed for weeks and months, many circumstances take place to prevent the possibility of reduction: the head of the bone acquires connections in its new and unnatural situation; the muscles become incapable of sufficient elongation again; and, what is worse, the articular cavity suffers more or less obliteration. In the ginglimoidal joints, an anchylosis is soon produced, and the reduction rendered impracticable. We have seen many attempts made with multiplied pulleys to reduce old dislocations. In a few instances, a degree of benefit was thought to have been the result; but in no instance was the success complete. These luxations, however, might have existed an unreasonable length of time. It is difficult to pronounce exactly how long a dislocation of the arm or thigh must have happened, to justify the abandonment of all attempts at reduction. The celebrated French surgeon Delault succeeded by the prudent employment of force in reducing many cases which had existed for several months; and such facts call upon the practitioner not to give up at once every old dislocation as past relief. A patient's means of subsistence, for himself and his family, will often entirely depend upon his luxation being reduced. In the ginglimoidal joints, as we have already observed, luxations sooner become irreducible: according to Boyer, after twenty, or four-and-twenty days, they, in general, cannot be replaced, owing to an anchylosis having occurred.

The surgeon knows, that a luxation is reduced by the limb having recovered its natural length, shape, and direction, and

by its having regained the power of performing certain motions impossible during the dislocation. For some time after the reduction the limb should not be moved, except with the utmost caution: a recurrence of a dislocated shoulder has been known to arise from carrying the hand inadvertently to the forehead, by a semicircular motion.

The cessation of pain has been considered as a sign of the reduction being effected; but, as Boyer has justly remarked, by cessation, we are to understand a considerable diminution, rather than a total discontinuance of pain.

Lastly; one of the most unequivocal and satisfactory indications of the reduction being accomplished, is the particular noise made by the head of the bone when it slips into the articular cavity again.

After a dislocation has been reduced, the grand object that now presents itself, is to keep the joint motionless, so as to hinder a relapse, and give the torn ligaments an opportunity of growing together again. All motion of the limb is, therefore, to be prevented. As the humerus cannot be luxated, except when it is at some distance from the body, a return of its dislocation will be effectually prevented by tying the elbow to the side of the body. The bandage employed for keeping the limb motionless, should always be made to operate principally on the end of the bone most remote from the joint affected. Thus, after a luxation of the arm, when we apply to the elbow the means for keeping the bone in its place, we act on that point of the humerus the most distant from its articulation with the scapula, and the force thus applied to the extremity of the lever, acts with much more effect. The same rule should be observed in the application of a bandage to the chin, after a luxation of the jaw. Indeed, in this last case, such practice has been recommended by all surgical writers; but in dislocations of the shoulder and hip, they seem to have forgot the utility of the principle, and have generally advised that most inert bandage termed the spica, which only acts on the centre of motion, and, consequently, can have little or no effect in keeping the bone fixed.

When a luxation arises from an internal cause, such as paralysis of the muscles, a looseness of the ligaments, or general debility, the duty of the surgeon is to endeavour to obviate the cause by suitable remedies, as well as replace the bone. We confess, however, that we know of no medicine nor application that seems to be calculated to remove a lax state of the ligaments.

Luxations, in general, are particularly liable to be accompanied by more or less contusion of the soft parts; and they are sometimes complicated with inflammation, rupture of blood-vessels, injury of nerves, and even a fracture. The latter complication is not frequent, but when it does occur, the bone has always been luxated first, and afterwards broken by the violence. The paralysis arising from a contusion of the nerves is not an uncommon consequence of dislocation of the shoulder; and when we consider the relation between the head of the humerus and the brachial plexus, the occurrence is by no means surprising.

Boyer observes, that when a luxated bone is not reduced, sometimes it remains in the place into which it has been forced; but much more frequently it changes its situation, and is carried still further from the cavity of the joint by the action of the muscles. Thus, in luxations of the thigh upwards and outwards, the glutei muscles continue to draw the head of the thigh-bone up along the dorsum of the ilium, until the limb is shortened as much as the parts will allow.

But, as the same surgeon has explained, whether the head of the luxated bone preserves its first position, or takes another,

it becomes flattened on that surface, by which it is in contact with a subjacent bone, while this last has a kind of depression gradually made in it. In some instances the original cavity of the joint diminishes in depth, especially when the head of the bone remains near its circumference. The muscles, impeded in their action, lose their consistence, assume a ligamentous appearance, and even become attached to the ligaments by a deposition of ossific matter, and, in this manner, a bony case is formed, which constitutes, with the displaced bone, a new articulation.

When a bone is not reduced, the limb remains deformed, and scarcely any use can be made of it for some months; but in time it approaches rather more to its natural direction, and when a new joint is formed, is yet capable of a considerable latitude of motion. In general, however, in consequence of the motion of the limb being more or less obstructed, the muscles fall away, and the limb has a weak and less bulky appearance than that of its fellow. When a dislocation in a child is left unredressed, this difference between the size of the luxated limb and that of the sound one, becomes very remarkable as the patient grows up to the adult state.

We shall now treat of particular dislocations, and afterwards conclude with some observations on compound luxations.

Luxations of the lower Jaw-bone.—When the mouth is widely opened, the condyles of the lower jaw advance forwards upon the eminentie articulares, and in this state may be made to slip under the zygomatic processes by very slight causes. This bone is only liable to be luxated in this one direction, whether one or both condyles escape from the glenoid cavities of the temporal bones. Every luxation, except that forwards, is rendered impossible by the natural conformation of the parts. A dislocation backwards is opposed by the ossific portion of the auditory canal; and luxations laterally, to the right or left, are prevented by the resistance arising from the spinous processes of the sphenoid bone and the ligaments of the joint. But it must be confessed, that the principal strength of the articulation of the lower jaw does not depend upon these ligaments; but rather on the muscles, and the particular conformation of the bones. The very shape of the lower jaw at once informs us, that a blow on its sides must be more likely to break it, by increasing its curvature, than dislocate it.

According to Boyer, luxations of the lower jaw cannot happen in very young infants, on account of the body and rami of this bone meeting at an obtuse angle, and, consequently, the condyles and necks having nearly the same direction as the rest of the bone, so that a luxation cannot be caused by any possible depression of the chin. Dislocations of the jaw are seldom caused by external violence; almost always by excessive yawning, or laughing.

The condyles of the maxilla inferior, being thrown before the transverse roots of the zygomatic processes, compress the deep-seated temporal nerves, and those going to the masseters. This fact affords a better explanation of the pains attending a luxation of the jaw, than the tension and elongation of the masseter and other muscles.

Besides great pain, a more instructive symptom of this accident is the mouth being much open, and incapable of being shut. These circumstances are more evident in recent than old luxations of the jaw. An empty space may be felt before the ears in the natural situation of the condyles. The coronoid process forms under the cheek bone an eminence, which is perceptible through the cheek, or by introducing a finger into the mouth. The cheeks and temples are flattened by the lengthening of the temporal, masseter,

and buccinator muscles. The saliva flows in large quantities from the mouth, the secretion being augmented in consequence of the exciting irritation. The arch formed by the teeth of the lower jaw is placed anteriorly to that made by those of the upper jaw. Lastly; during the first days of the luxation, the patient can neither speak nor swallow.

We have already adverted to one condyle being sometimes dislocated, while the other remains in its proper place. According to Mr. Hey, it is not always easy to know when this is the case. "One would expect," says this practical writer, "from a consideration of the structure of the parts, and from the description given in systems of surgery, that the chin should be evidently turned towards the opposite side; but I have repeatedly seen the defeat, when I could discern no alteration in the position of the chin. The symptom which I have found to be the best guide in this case, is a small hollow, which may be felt just behind the condyle that is dislocated, which does not subsist on the sound side." *Pract. Observ. in Surgery*, p. 325, edit. 2.

When the luxation is recent, the above symptoms enable us to ascertain the nature of the accident with sufficient ease; but when the dislocation has existed several days or weeks, the case becomes less strongly marked. The lower jaw has insensibly approached the upper one; and the patient gradually recovers the faculty of speech and deglutition; but he still stammers, and drivels.

Hippocrates pronounced luxations of the jaw to be fatal, unless reduced before the tenth day; but surgeons have now found, that this sentiment is not well founded, and it is even suspected, that Hippocrates might confound cases of locked jaw with those of dislocations.

When the jaw has once been dislocated, the accident is more prone to be produced again by slight causes. Mr. Hey mentions his having known two persons in whom this dislocation frequently happened. Not only yawning, but even opening the mouth incautiously in eating, would cause the accident. P. 326, edit. 2.

When a luxation of the jaw is to be reduced, the patient should sit on a low stool, with his head resting on the breast of an assistant. In this position of the patient, the surgeon's hands are on a level with the mouth, which is advantageous, because he is not obliged to elevate them, and consequently can act with greater force on the jaw. The surgeon, after guarding his thumbs with linen, or a thick pair of gloves, is to introduce them into the mouth, and place them as far back as possible, on the great molars, at the same time bending under the chin the four fingers of each hand. The jaw, being thus grasped, is to be moved in the manner of a lever, the grinders being pushed downwards and the chin upwards. No sooner are the condyles thus extricated from under the zygomatic processes, than the muscles draw them up into their proper places again, with considerable force and suddenness. This takes place so rapidly, that the surgeon's thumbs would be in danger of injury, if he were to neglect to move them quickly outwards, and place them between the cheek and the jaws.

After the reduction, the four-tailed bandage for the lower jaw is to be applied, as in cases in which this bone is broken. (See *Plate V.*) In the plate just referred to, however, it is proper to mention, that the centre of the bandage should have been placed exactly on the chin, an essential circumstance, as this is the point farthest from the centre of motion, and consequently that where the bandage can operate with the most power in keeping the bone motionless. During the first days, the patient should only be allowed liquid food, or such as requires no mastication.

When unusual difficulty occurs in disengaging the condyles from under the zygomatic processes, owing to the resistance of the muscles, Le Cat's plan for overcoming and fatiguing these powers may be pursued; it consisted in introducing a small stick between the teeth, and using it as a lever for combating the action of the muscles, until they were quite exhausted. Here the surgeon is not required to use violence, which might break the teeth, but only to keep up a moderate and unremitting extension of the resisting muscles.

According to Mr. Hey, if both sides of the lower jaw are depressed, while one side only is dislocated, the reduction of the luxated condyle is rather prevented. The force should be applied to the affected side alone. See *Pract. Observ. in Surgery*, p. 326, edit. 2.

Luxations of the Vertebrae.—The large surfaces by which these bones touch each other; the number and thickness of their ligaments; the strength of the muscles lying on the column formed by them; the small motion of which each vertebra is capable; and, lastly, the vertical direction of their articulating processes (says Boyer), render a luxation of them in the dorsal and lumbar part of the column entirely impossible. A violence, though ever so considerable, cannot displace them, without first fracturing them. But this is not the case with the cervical vertebrae; the extent of their articulating surfaces is less; the ligamento-cartilaginous substance which unites their bodies has more pliability; the motion of their articulations is greater; and their articulating surfaces have an oblique direction, which allows them to have an obscure rotatory motion. Hence luxations of the cervical vertebrae sometimes present themselves in practice. Boyer has seen a luxation of the middle cervical vertebrae caused by a violent rotatory motion of these bones.

Luxations of the Head from the first Vertebra.—The joints between the occipital bone and first vertebra of the neck, or atlas, are strengthened with numerous ligaments, and only admit of very limited motion. We have no instance of luxation of the head from the first vertebra by an external cause, and such a dislocation, were it ever to happen, would instantly destroy the patient, by compressing and injuring the spinal marrow. But, as Boyer has remarked, nature, which cannot bear so sudden a change, is habituated to it, when it takes place gradually, and the spinal marrow which would be fatally hurt by a sudden dislocation of the head from the atlas, is capable of bearing the same kind of luxation that is insensibly and slowly produced by disease.

Luxations of the first cervical Vertebra from the Second.—The motion of the head to the right and left is principally executed by the first vertebra turning on the second. The laxity and weakness of the ligaments between these bones, and the direction of their articular processes, tend to facilitate this kind of rotation, which motion, indeed, would frequently be carried beyond due bounds, and a dislocation happen every time that we turn our heads, were not the motion confined by the very thick ligaments which go from the sides and summit of the process dentatus of the second vertebra to the edges of the great occipital hole. As Boyer observes, when this motion is forced beyond its proper limits, the ligaments are torn, and the lateral parts of the body of the first vertebra glide along on the articulating horizontal processes of the second. If the head is turned from the left to the right, the left side of the body of the vertebra is carried before its corresponding articulating surface, whilst the right side falls behind its corresponding surface. In this luxation, sometimes the process dentatus, the ligaments of which are broken, leaves the ring, formed for it by the transverse ligament and the anterior arch of the first vertebra, and presses on the spinal marrow.

In other examples, it does not quit the ring; but the diameter of the vertebral canal is always diminished at the place of the dislocation, and the spinal marrow injured or lacerated. It is readily conceivable, that the patient cannot survive an accident of this nature, every wound of the spinal marrow, in so high a situation, being quickly fatal.

The celebrated M. Louis found, that the criminals who were in his time hanged at Lyons, perished by the luxation of the first vertebra from the second; whilst those hanged at Paris were suffocated by strangulation. He discovered that the cause of this difference was owing to a rotatory motion which was given to the body of the culprit by the executioner at Lyons, the moment it was suspended. J. L. Petit mentions an instance in which a boy, between six and seven years of age, was killed in an instant by a luxation of the first from the second vertebra, brought on by the boy struggling, whilst a person was rashly lifting him up by the head. This last trick cannot be too severely condemned as a most dangerous experiment.

There are other luxations of the neck not followed by death; but in these cases, the dislocation takes place in the third, fourth, fifth, or sixth vertebra, and only one articulating process is luxated. Some examples are quoted by Boyer, which were considered as cases of this last description, being attended with a distortion of the head to the right or left, without any spasm or rigidity of the sterno-cleido-mastoideus muscle.

When luxations of the cervical vertebrae produce no symptoms indicating a dangerous degree of pressure on the spinal marrow, it is prudent not to attempt the reduction, as the patient may be killed in a moment by the endeavour, in consequence of the spinal marrow becoming suddenly compressed and injured. If the symptoms, however, make it probable that the patient's only chance of life depends on altering the position of the luxated bones, the surgeon ought cautiously to attempt the reduction. Fortunately, these cases are as unfrequent as they are perplexing, and we shall omit, as uninteresting to the practical surgeon, the usual directions respecting the mode of reducing such accidents. It is enough for the surgeon to be duly aware of the peril that accompanies the attempt.

Luxations of the Bones of the Pelvis.—These bones are scarcely susceptible of luxations. The os sacrum, firmly fixed between the two ossa innominata, cannot possibly be dislocated. The os coccygis is more easily fractured than luxated. The latter accident, however, has sometimes been observed. Boyer has seen it induced by sloughing and disease, which denuded the bone, and evinced that there was a space of nearly two inches between the extremity of the sacrum and the base of the os coccygis. But, in the end, the two bones grew together again. Much has been written by authors concerning a relaxation and yielding of the symphysis pubis and sacro-iliac articulations in the advanced stages of pregnancy. We leave to the accoucheur the determination of this matter, as it is only indirectly connected with the subject of luxations.

When we stated that the bones of the pelvis were hardly susceptible of luxations, our meaning was of course confined to the effect of ordinary causes. Great external violence, acting directly on any part, will make every thing yield. Thus, in the fourth volume of the *Memoirs of the French Academy of Surgery*, an instance is recorded, where the right os ilium was dislocated from the sacrum, three inches backwards, by a sack of wheat, weighing three hundred and fifty pounds, falling on the back of a labourer. The patient died on the twentieth day, and the luxation was proved by dissection. The pelvic viscera were found in a

Rate of inflammation, with matter in the lower region of the abdomen.

Were a similar accident to present itself to the practitioner, he ought to have recourse to antiphlogistic means; for the danger chiefly depends on the pelvic viscera becoming inflamed. Copious and repeated bleedings, the warm-bath, fomentations, and low diet, would be particularly indicated.

Luxations of the Ribs.—The ancient writers on surgery have furnished us with no observations concerning dislocations of the ribs, and observers, who have published numerous facts relative to other cases, make no mention of these accidents. Even J. L. Petit and Duverney, authors of more recent date, are silent on the subject; and as Paré, long before them, had distinctly treated of luxations of the ribs, we must ascribe their silence to their disbelief in the possibility of such cases.

Whether the ribs are susceptible of dislocation or not, is yet an unsettled question.

Ambrose Paré, Barbette, Junker, Platner, and Heister, describe the accident as possible. Platner has observed: "*Costæ longè frequentius franguntur, quàm à suâ fede moventur. Non possunt in anteriorem partem excidere, cum oppositi processus transversii vertebrarum summam illarum partem continent, nec facile sursum vel deorsum versus promoveri possunt. Igitur si moventur in anteriorem partem propelluntur.*" *Instit. Chir.* § 1149. Platner actually enters into a detail of the symptoms to be apprehended in such case: "*cùm pleura prematur, gravis inflammatio et spirandi difficultas sequitur.*" In a memoir inserted amongst those of the Royal Academy of Surgery in France, M. Buttet is yet more positive than Platner, in only admitting the luxation forwards; but he does not conceive that the accident can happen to all the ribs with equal facility. The upper ones are protected by the scapula, and the lower, which are unfixed and very moveable, can only be luxated with great difficulty. He thinks that dislocations can hardly occur to any of these bones, except the four or five lower true ribs, and two or three of the upper false ones, which last are more susceptible of displacement, in consequence of not being supported by the sternum. On the other hand, Boyer, a late writer on dislocations, is very positive that the ribs are exempt from these accidents. He tells us, that he should have observed the same silence on the subject as J. L. Petit, did not a case, published in the *Memoirs of the Academy of Surgery*, after the death of that celebrated practitioner, seem to establish the possibility of such cases. But Boyer contends, that, in reading this example, it is obvious the surgeon has mistaken a fracture of the posterior end of the ribs for a dislocation. If, says Boyer, we attend to the number and force of the ligaments, which attach the ribs to the vertebræ and sternum, and also to the manner in which the intercostal muscles confine them, we shall not easily conceive how external violence, whether it acts on their middle or extremities, can luxate them. They are so firmly attached to the surrounding parts, that it is very difficult to separate them from the body in the dead subject; and, in preparing skeletons, we often break those bones, if we are not careful to cut all their bonds of union, before we attempt to detach them from the parts with which they are articulated. All the symptoms accompanying M. Buttet's case indicate a fracture of the neck, or posterior extremity of the rib, as the pain, crepitation, and motion of the bone. No conclusion could be drawn from the motion, in proof of a luxation, since the fracture (if it were such) was situated very near the back end of the rib,

and, of course, the whole length of the bone would seem to move at once.

Boyer excludes from consideration cases, called by Lieutaud and others dislocations of the ribs, which, in fact, are only separations of the ribs and dorsal vertebræ from each other, in consequence of the destruction of their ligaments, &c. by disease.

Luxations of the Clavicle, or Collar-Bone.—Luxations of the clavicle are much less frequent than fractures; and it was estimated by Default that the latter accidents are to the former as six to one. As far as our own experience enables us to judge, dislocations are even more uncommon than this calculation represents.

The clavicle, however, may be luxated either from the sternum, or the acromion.

Luxations of the sternal End.—The sternal end of the clavicle may be dislocated forwards, backwards, or upwards, but never downwards, in which last direction a luxation is prevented by the cartilage of the first rib. The dislocation forwards is by far the most frequent, and may be caused by excessive motion of the scapular end of the clavicle backwards. Luxations upwards and backwards are very rare. The former can only be occasioned by the shoulder being pushed violently forwards and downwards, which sometimes happens in falls. The dislocation backwards is the most unusual case of all.

If the shoulder is pushed violently backwards, the sternal end of the clavicle is propelled forwards, tearing the capsule of the articulation, the anterior ligament, and the tendon of the sterno-cleido-mastoideus muscle. Quitting the surface with which it is articulated, it slips in front of the upper part of the sternum, and produces under the skin in this situation, a hard prominence, which follows the motion of the shoulder.

When the shoulder is suddenly depressed, the sternal end of the clavicle is easily luxated upwards, as there is nothing to limit its motion in this direction, except the inter-clavicular ligament, which, being relaxed by the greater contiguity of the two bones, is not capable of making effectual resistance.

In the luxation backwards, the extremity of the clavicle is carried behind the superior part of the sternum.

The superficial situation of the clavicle renders easy the diagnosis of all luxations of its sternal end. When the dislocation happens forwards, a hard projection is felt, or even seen on the anterior and superior part of the sternum. Such projection may be made to disappear by carrying the shoulder forwards and outwards. In the place which the head of the clavicle ought to occupy, an empty space is perceptible.

In the luxation upwards, the distance between the sternal ends of the two clavicles is lessened.

If the luxation is backwards, the head of the bone forms a tumour at the interior and inferior part of the neck, and a depression may be felt in the place which it ought to occupy. The head of the bone thus displaced, may, as Monsieur J. L. Petit has observed, compress the trachea, œsophagus, jugular vein, carotid artery, par vagum, &c. so as to cause dangerous symptoms. It is also to be noticed, that, in dislocations of the sternal and of the clavicle backwards, the head is inclined towards the affected shoulder.

Luxations of the sternal extremity of the clavicle may be reduced by making a lever of the arm, by means of which the shoulder is first to be brought outwards, and then pushed forwards, supposing the dislocation to have happened in that direction. But if the luxation is backwards, the

shoulder, after being drawn outwards, must be carried backwards; or upwards, when the dislocation is in the same direction. By observing these rules, the head of the bone may be replaced, with the aid of a little pressure of the thumb. But though the reduction may be easy, it is difficult to maintain it, all the ligaments being torn, and the articular surfaces disposed to slide away from each other, on the slightest motion of the shoulder.

The apparatus used by Default for fractures of the clavicle is to be employed in luxations of the sternal end of the bone. (See *Fractures of the Clavicle*, and *Surgical Plate IV.*) The shoulder continues to be kept outwards by means of the cushion placed in the axilla: but notwithstanding the utmost attention on the part of the surgeon, the head of the clavicle cannot be prevented from being somewhat more prominent than that of the opposite side. Bradon proposed a tourniquet for making pressure on the luxated extremity of the bone, with a view of hindering such deformity, though, according to Boyer, it will not answer the purpose.

Luxations of the Scapulary End of the Clavicle.—These cases are much less frequent than the former, owing to the very great strength of the ligaments binding the clavicle to the scapula. The scapulary end of the clavicle is seldom luxated in any direction except upwards. Boyer admits the possibility of the accident taking place downwards, and we think we have seen an instance, in which it was caused by a heavy brick falling on the shoulder from a considerable height. There was no crepitus, and the end of the bone, which was moveable, was obviously depressed below the acromion.

The dislocation upwards is that, which principally demands the attention of the practitioner. It may be caused by falls, in which the violence operates on the extremity of the shoulder. The scapulary end of the bone slips upwards over the acromion, which last process is itself a little drawn under the luxated part of the clavicle, when the shoulder is pulled inwards by such muscles, as have the effect of bringing the arm towards the trunk. The writer of this article was lately consulted in a very manifest case of dislocation of the scapulary end of the clavicle. The patient was a young gentleman out of Yorkshire, where the accident had happened, and, not being understood, was left unredressed. When the case was brought to us, it was too late for any assistance to be rendered. Fortunately, the inconveniences suffered were not very great. The patient generally inclined his head towards the affected shoulder, and experienced a degree of weakness in raising his arm to his head; but even these infirmities were gradually becoming less.

Boyer conceives, that a violent action of the trapezius muscle, which we know is attached to the outer half of the clavicle, may have a share in producing this kind of dislocation, especially if the muscle should forcibly contract just at the moment when the acromion is fixed on the ground or body, against which it falls.

The diagnosis of the accident cannot be very difficult, since the end of the clavicle may always be distinctly felt, forming a projection under the skin that covers the acromion. The head is inclined to the affected side, and the patient avoids moving the arm, in consequence of such action occasioning pain.

The dislocation is to be reduced by drawing the arm and shoulder outwards, and pushing the displaced end of the clavicle downwards. Default's apparatus for broken collar bones is then to be applied. (See *Fracture of the Clavicle*, and *Plate IV.*) The cushion in the arm-pit, when

the elbow is confined near the side with the roller, here acts very usefully in keeping the shoulder outwards. The turns of the bandage, which go from the elbow to the shoulder, should also be made to act especially on the outer end of the clavicle, so as to press it downwards.

Luxations of the Shoulder; or of the Humerus, or Os Brachii, from the Scapula.—The shoulder joint allows the arm to be moved in every possible direction, and as the structure, essential to so great a latitude of motion, hinders the articulation from being endued with the strength and stability of other less moveable joint, it becomes, of course, a very pre-disposing cause of dislocations. In fact, no joint is so frequently luxated as the shoulder. And it appears from a comparative register, kept at the Hôtel Dieu at Paris, that, during several years dislocations of this articulation equalled in number the luxations of all the other joints together. *Cœuvres de Default par Bichat*, tom. i. p. 341.

Every thing, says the author of the preceding work, appears to facilitate the escape of the bone from its natural cavity. 1. In the articular surfaces, a shallow oval cavity, which receives a semi-spherical head twice as extensive as itself in the perpendicular direction and thrice as broad from before backwards. 2. The only ligament, strengthening this joint, is a mere capsule, which is thin below, the very direction in which there is nothing to oppose a luxation, and thicker above, where the acromion and coracoid processes, together with the triangular ligament, form an almost insurmountable obstacle to such an accident. 3. With respect to the muscles and motions of the shoulder, we have to notice numerous and strong fasciculi around the joint, communicating to it movements easily performed in every direction; propelling the head of the humerus against different points of the capsule; and rupturing the latter part, when their power is superior to its resistance. 4. As for external force, what bone is more exposed to its effects, particularly in the labouring classes of society?

Affected by so many different pre-disposing causes, the humerus would be incessantly subjected to dislocations, did not the scapula, which is equally moveable, follow all its motions, and afford it a point of support differently disposed, according to the different position of its upper end. In short, much of the strength of the joint depends upon the double moveableness of the two articular surfaces.

Of the different Kinds of Luxations of the Shoulder.—Though this joint is generally much disposed to luxations, it is not equally so at every point. There are some points at which the accident cannot happen at all; while there are others at which, though it seems possible, it has never been observed. Hence, before examining the mechanism of dislocations of the shoulder, Default endeavours to determine with precision the directions in which the accident is possible. He adverts to the confusion existing among writers on this subject; some of whom employ different terms to express the same thing; while others have affixed similar names to things which are essentially different and distinct from each other. With regard to some kinds of luxations they all coincide; concerning others, they disagree! Default first divides Luxations of the humerus into two kinds; *viz. primitive*, which are the sudden effect of external violence, and *conjective*, which succeed the former from causes hereafter to be explained.

The same eminent surgeon then directs us to suppose the oval surface of the glenoid cavity to have four straight lines drawn at its sides, in the form of a parallelogram; one representing the upper edge of that cavity; another, the

LUXATION.

the inferior; a third, the internal; and a fourth, the external.

It is manifest, that the head of the humerus cannot be displaced towards the upper edge of the glenoid cavity. In that direction the acromion and coracoid processes, the triangular ligament stretched between them, the tendons of the biceps and supra-spinatus, and the fleshy part of the deltoid muscle, form an effectual resistance to any force propelling upwards the head of the bone. Supposing a luxation in this direction were to happen, the head of the bone must also be pushed outwards, a thing which is impossible, because the trunk hinders the elbow from being inclined far enough inwards for that purpose.

On the other hand, the three remaining edges present but little resistance. At the lower one, the long portion of the triceps; at the internal one, the tendon of the subscapularis; and at the external, the tendons of the infra-spinatus and teres minor; easily yield to a force directed against them, and admit of primitive luxations taking place, either downwards, inwards, or outwards; downwards, between the tendon of the subscapularis and that of the long head of the triceps; inwards, between the subscapular muscle and fossa; and outwards, between the infra-spinatus muscle and subjacent part of the scapula. All these modes of displacement do not occur with equal frequency, as will be presently considered.

After the head of the humerus has quitted the glenoid cavity, and slipped in one of these three directions, it often changes its situation again; and, in this event, a consecutive luxation may follow a primitive one, either downwards, or inwards; but never that outwards, were such a case to occur, because the spine of the scapula would prevent it.

According to Default, a consecutive luxation inwards may succeed a primitive one downwards, as there is nothing to hinder the head of the bone from passing between the subscapular muscle and fossa. On the contrary, should it tend outwards, the tendon of the triceps resists, and, notwithstanding the statement of Petit, a consecutive luxation in this last direction never happens.

Sometimes, when the head of the humerus has escaped at the internal or inferior part of the capsule, it is carried behind the clavicle, so as to form a consecutive luxation upwards, a case which was noticed by Paré, perhaps by Galen, and a specimen of which was preserved in Default's museum. Here the secondary displacement only takes place slowly, and after it has happened, art can seldom correct it, on account of the firm adhesions contracted by the surfaces of the bone. Thus, in the example referred to, a new cavity was formed behind the clavicle, and the humerus was connected with the surrounding part by a kind of new ligaments.

From this statement, derived from Default, it follows that the humerus is subject to four sorts of displacement: 1, downwards; 2, outwards. In these directions the dislocation is always primitive. 3, Inwards, which may be either primitive or consecutive. 4, Upwards, in which direction the accident can only happen consecutively. As Default observes, the second and the fourth cases are exceedingly rare, compared with the rest.

Primitive Luxations.—These are caused by falls or blows on the arm, and the kind of dislocation appears to be determined by the position in which the limb happens to be at the moment of the accident.

If the arm is more or less raised from the trunk, without being inclined either forwards or backwards, and the patient falls laterally, the weight of the body, being almost entirely supported by the humerus, forces downwards its upper end,

which lacerates the capsular ligaments, and is dislocated downwards. The occurrence is also in part facilitated by the united action of the latissimus dorsi, pectoralis major, and teres major muscles. These are in a state of involuntary action, and tend to draw downwards the head of the humerus, while the elbow remains fixed on the ground or surface against which it has fallen. Some authors believe, that a violent contraction of the deltoid muscle may also have a share in luxating the shoulder downwards, as it may tend to force the head of the humerus through the capsular ligament towards the axilla. Default thinks the truth of this statement is confirmed by many observations, and quotes the case of a notary whose shoulder was dislocated downwards, in lifting up a heavy register book.

The manner in which a primitive luxation inwards is produced, is little different from that of the foregoing case. The elbow, at the moment of the fall or blow, is both separated from the trunk and carried backwards. The weight of the body acts upon the humerus, the anterior portion of the capsular ligament gives way, and the head of the bone is dislocated forwards.

The luxation outwards can only be occasional when the elbow is inclined forwards, towards the opposite shoulder. If the force is sufficient, the great, the outer part of the capsular ligament is lacerated, and the head of the humerus displaced. But, says Default, what can such power be? In a fall, when the arm is forced against the side, it cannot be moved far enough to cause a laceration of the capsule. Hence this eminent surgeon concluded, that luxations of the head of the humerus outwards must be very uncommon cases. None are recorded by surgical writers, and Default himself had never observed such an accident. Besides, it is worthy of attention, that when in falls, the arm separated from the side is inclined either forwards or backwards, the weight of the body only operates upon it obliquely, and it is little acted upon by the latissimus dorsi, pectoralis major, and teres major muscles. Hence no dislocations of the shoulder are so frequent as those downwards, in the production of which cases the influence of the weight of the body, and of the action of the muscles is direct. However, the luxation inwards is not uncommon, and many of Default's cases prove the possibility of a primitive dislocation of this kind, notwithstanding several modern authors have doubted it, by believing with Hippocrates, that originally all luxations of the shoulder happen downwards.

It sometimes happens, that the lacerated opening in the capsular ligament suffices for the passage of the head of the bone from the glenoid cavity, but immediately afterwards contracting, is not large enough to admit of its return. This practical fact was first noticed by Default, who has published two examples of it in his journal. Such cases have since been very frequent at the Hôtel Dieu, at Paris.

Consecutive Luxations.—When a consecutive luxation succeeds a primitive one, many causes may concur in producing this change. If a second fall should happen, the elbow being separated from the side, the head of the bone may easily be forced out of the place into which it was first thrown. A case illustrating this observation is related in Les Œuvres Chir. de Default par Bichat, tom. i. p. 350.

The action of the muscles is a permanent cause of a new displacement. When the humerus is dislocated downwards, the pectoralis major, and the inner portion of the deltoid, pull its upper portion inwards and upwards.

Various movements communicated to the arm may also produce a change in the position of the luxated head of the bone, according to their direction. Thus a luxation in-

wards.

wards has frequently succeeded one downwards, in consequence of awkward efforts to reduce the bone.

Symptoms of Luxations of the Shoulder.—In general, the diagnosis of luxations of the shoulder is not attended with much difficulty. As Hippocrates has observed, whatever may be the mode and situation of the displacement, a manifest depression may always be perceived under the acromion, which process seems to project more than in the natural state. Moving the humerus is very painful, and indeed most of its motions are either impeded, or very much limited. The arm cannot be moved without the shoulder being also moved, because, the functions of the joint being prevented, both these parts form as it were only one.

To such symptoms, common to all dislocations of the shoulder, are to be added those which belong to particular cases. If the luxation is downwards, the arm is somewhat longer than in the natural state; it may be moved a little way outwards; but every attempt to carry it forwards or backwards inevitably occasions acute pain. The elbow is more or less raised from the axis of the body by the action of the deltoid, the long portion of the biceps, and the supraspinatus muscles, which, being on the stretch, contract and incline the bone outwards. In order to avoid the pain arising from this position, the patient leans towards the affected side, keeps his fore-arm half-bent, and rests his elbow on his hip, so that the arm may have a fixed point to hinder all painful motions of the limb. By this attitude alone, Default was accustomed to recognize a luxation downwards, and he was seldom deceived. Besides these circumstances, we have to mention, that the dislocated head of the bone always produces a hard and more or less evident prominence in the hollow of the axilla.

In addition to the symptoms common to all luxations of the shoulder, the dislocation inwards presents the following: the elbow is separated from the side, and carried a little backwards; the humerus appears to be directed towards the middle of the clavicle; moving the limb backwards is not very painful, but carrying it forwards is exquisitely so; a manifest prominence may be noticed under the pectoral muscle; the arm is scarcely longer than in the natural state; and the patient's attitude resembles that of the foregoing case.

Were a dislocation outwards ever to happen, it would be particularly characterized by a hard tumour under the spine of the scapula, by the inclination of the elbow forwards, and its separation from the side; and, lastly, by the length of the limb appearing a little increased.

A luxation upwards would be announced by a projection behind the clavicle, an obvious shortening of the arm, and its unnatural direction.

It is frequently much more easy to ascertain the existence, than the species, of luxation of the shoulder. Indeed, sometimes it is a most difficult matter to determine, whether a dislocation inwards is primitive or consecutive, as the apparent phenomena of each case are alike. The judicious and experienced Default taught, that this interesting point is only capable of being elucidated by attention to the history of the case, and the order in which the symptoms presented themselves. This excellent surgeon represents the distinction as of much practical importance, since the proper mode of reducing the two cases is different, the head of the bone having to describe a very short track in the primitive luxation, and a more circuitous one in that which is consecutive.

Dislocations of the shoulder do not commonly give rise to any accidental bad or troublesome symptoms. Sometimes, immediately after the occurrence, the joint is affected with a great deal of swelling; but this complaint generally subsides very quickly, under the use of the aqua vegeto-mineralis.

In certain instances, the pressure of the head of the bone on the axillary glands and veins produces an œdema of the whole limb. Default seldom observed this happen, except where the reduction had been delayed. The treatment he recommends is to apply a roller to the limb, after reducing the head of the bone.

Another accident, which was several times observed by this distinguished surgeon, is a paralysis of the limb, occasioned, in the luxation inwards, by the pressure of the head of the bone on the axillary plexus of nerves. In some instances, this affection proved incurable; in others, it yielded to the employment of strong ammoniacal liniments. A few obstinate cases were cured by making an issue just over the clavicle by means of the moxa; but this last method was as frequently unavailing as successful.

Reduction of Luxations of the Shoulder.—The infinite variety of modes proposed for reducing dislocations of the shoulder may be referred to two general classes. Some consist in replacing, by a mechanical force, the head of the humerus in the cavity from which it has escaped, whether previous extension be made or not. Others are restricted to disengaging the head of the humerus from the situation which it accidentally occupies, and the reduction is left to be accomplished entirely by the action of the muscles.

The history of all the methods intended to operate on the first principle would be tedious and unprofitable. Suffice it to state, that almost all of them act in the following manner. Something being placed under the axilla, serves as a fulcrum, on which the arm is moved in the way of a lever, the resistance being the luxated head of the humerus, and the power being applied either to the lower part of this bone or to the wrist. It was in this manner that the ambli of Hippocrates acted, that machine so renowned even in modern times, and of which numerous modifications have been devised by Paulus Ægineta, Ambrose Paré, Duverney, Freke, &c. By such an apparatus, the head of the humerus was at once directed towards the glenoid cavity of the scapula, and disengaged from its unnatural situation.

Extension of the arm usually produces this second effect, and has been accomplished in a variety of ways. Sometimes the weight of the body on one side, with the dragging of the dislocated limb on the other, served to make the extension. It was on this principle that the ladder, the door, and the stick operated, as described by Hippocrates in his treatise on fractures, and repeated by all subsequent writers. On other occasions, the trunk has been immovably fixed, while the arm was forcibly extended. This was the mode pursued in employing the machines described by Oribasius.

Sometimes no perceptible extension at all was made, and the head of the humerus, being propelled outwards by something put under the axilla, was pushed by the surgeon at once into the glenoid cavity.

With Default, we shall abstain from entering into a particular explanation of the objections to the preceding methods. Petit and B. Bell have already detailed their disadvantages. Whoever considers that the head of the bone has escaped through the ruptured and lacerated capsular ligament, and that it is impossible to know precisely the exact situation of the opening, must perceive how absurd it is to attempt to direct the head of the bone to it by any artificial force.

However well covered with soft materials the body may be, which is put under the axilla for the purpose of serving as a fulcrum, an unpleasant chaffing, or even dangerous degrees of stretching and laceration, may arise from its application, when the trunk is suspended over it, as in the employment of the door, stick, &c. By such practice, Petit saw the

the neck of the humerus fractured, and the axillary artery ruptured, so that an aneurism was the consequence.

A wife objection, also made by Default to the use of any apparatus of the foregoing kinds, is, that few surgeons are provided with the instrument, and therefore much useful time would be lost in procuring it, when the ease is actually waiting for relief. Besides, says he, when the luxation is consecutive, how can any mechanical contrivances have the effect of drawing back the head of the bone through the track by which the displacement has taken place? For instance, if a luxation inwards has succeeded one downwards, the head of the bone ought to be drawn downwards before being replaced in its natural cavity. How can the direction of the extension be varied accordingly? It is likewise to be observed, that every apparatus alluded to refits the action of the muscles, which, in fact, ought to be the principal agent in the reduction. Were a luxation ever to happen upwards, no apparatus could answer, as must be most evident.

No doubt, however, when the head of the humerus is luxated downwards, and is not situated far from the glenoid cavity, the machines to which we have alluded will often serve to effect the reduction with tolerable facility. But in such cases, there is no real occasion for artificial contrivances, as natural means will be found quite sufficient. In short, the reduction may be executed with the hands, and with this advantage, that the direction of the movements may be regulated and varied with more precision.

The following method was frequently pursued by Default with success: the patient sat on a chair of middling height: Default placed the hand of the luxated limb between his knees, which he moved backwards, so as to make extension, and disengage the head of the bone, while an assistant held back the trunk, and made the requisite counter-extension. Default now took hold of the upper part of the humerus with both his hands, and pushed its head upwards and a little outwards into the glenoid cavity.

This mode is mentioned by Petit, though complicated with the employment of a napkin, which was put under the axilla, and over the surgeon's neck, who forced upwards the head of the bone by drawing back his head.

In recent luxations of the shoulder downwards, Default sometimes often found even a more simple plan answer: he put his left hand in the axilla to serve as a fulcrum, while, with the right, which was applied to the lower and external part of the arm, he moved the humerus towards the trunk, at the same time pushing the bone upwards. By this double movement, directed upwards and outwards, the head of the humerus is put into its natural situation. See *Œuvres Chirurgicales de Default, par Bichat, tom. i. p. 363, 364.*

Mr. Hey notices, that if the head of the os humeri remains in the axilla, and not far removed from the glenoid cavity, the reduction may sometimes be executed with a very small degree of extension. Thus, in the relation of one case, he observes: "after I had put every thing in proper order for the reduction, I desired the assistants, who were to make the extension, to keep the arm elevated at a right angle with the body, till I should direct them to begin the extension. In doing this, they kept the arm a little upon the stretch, waiting for my orders. While the arm was in this state, I placed my fingers below the head of the bone, that I might be ready to co-operate with them; and pressing my fingers upwards into the axilla, that I might feel the head of the bone distinctly, the reduction was unexpectedly made by this gentle effort." *Pract. Observ. in Surgery, p. 295—226, edit. 2.*

The same experienced surgeon once saw a luxated shoulder

reduced by the mere efforts of the patient, who, while preparation for the reduction was making, walked about in pain, and after placing his hand on the back of a chair, and moving his body in different directions, cried out, as if hurt more than usual. He then sat down, and said that he was easy, and could move his arm better. In short, the bone was actually reduced. *P. 297. op. cit.*

Reduction of Luxations of the Shoulder by Means of Extension, as practised by Default.—There must be an adequate number of assistants, in order to increase, according to necessity, the force which is to overcome the resistance experienced; but, in general, two are quite sufficient. A thick pad should be procured, for the purpose of guarding the margins of the axilla from injury; and the assistants should be furnished with a sheet, doubled into folds, about four inches in breadth, and also with a towel folded in the same manner.

The patient is to sit on a lowish chair, or he may be laid on a strong immoveable table. Default long followed the first of these modes, according to ordinary custom, though, as Bichat remarks, it is not in every respect the most advantageous. In the sitting posture, indeed, the arm may be very well extended transversely; but if, as often happens, it is necessary to direct the extension upwards or outwards, the assistant, being then obliged to raise or lower himself, does not possess equal power in the new posture, and finds himself embarrassed, and incapable of varying the direction of the extension, according as the surgeon may think best.

As for the patient, he finds such posture, in which the trunk is only partly supported, much more irksome than that in which the chest lies equally upon an horizontal surface. Motives of this kind induced Default, in the latter years of his practice, to renounce the sitting position.

The patient's posture being arranged, the linen pad is to be put under the axilla of the affected side, and the middle of the folded sheet is to be placed on such compress, while the two ends are to be carried obliquely before and behind the chest to the opposite shoulder, where, being held by an assistant, they serve to fix the trunk, and to make the counter-extension. The pad hinders the sheet from pressing on the margins of the pectoralis major and latissimus dorsi. Were it not so, these muscles, being pulled upwards, would draw the humerus in the same direction, and defeat the extension, which is performed as follows.

Default made two assistants take hold of the fore-arm above the wrist, or else he caused the folded towel to be applied to this part, and confided to the care of one or two assistants, who were to begin the extension in the same direction in which the dislocated bone lies. This first movement, intended to disengage the head of the humerus from the place in which it happened to be lodged, was followed by another, which varied according to the kind of luxation. When the dislocation was downwards, Default gradually brought the arm near the side, at the same instant that he pushed it gently upwards. By this artifice, the head of the bone was inclined towards the glenoid cavity, into which it generally entered without difficulty.

When the luxation was inwards, the humerus was brought upwards and forwards, after the first extension in the direction of the bone: thus its head was directed backwards. Were a luxation to occur outwards, it would be necessary to move the humerus, during the extension, exactly in a direction opposite to that recommended in the foregoing instance.

As soon as the head of the humerus has been disengaged by the first extension, the movement communicated to the bone by the subsequent extension ought in general to be precisely in the contrary direction to that in which the head of the bone has escaped.

When

LUXATION.

When any difficulty seems to oppose the reduction, the bone should be moved in different directions, after the requisite extension has been made, with due attention to the principle just laid down. This method will frequently answer when simple extension will not, the head of the bone being conducted by the movements towards the glenoid cavity.

When the luxation was consecutive, Default, by means of the first extension in the direction of the dislocated bone, brought its head into the situation where it was originally lodged, and he then acted just as if the case were altogether a primitive one. Very often, whether the accident is of one kind or the other, can only be distinguished at the time of the reduction. In fact, when the extension is well managed, the reduction mostly happens spontaneously, and if the head of the bone is luxated inwards consecutively, it may be observed descending along the inside of the scapula, and then passing over the inferior part, and ascending towards the laceration in the capsule.

It has been stated that when the extension is properly managed, the reduction is effected almost spontaneously. Whatever may be the kind of primitive luxation, it is evident that the muscles surrounding the articulation are on one side stretched, and on the other relaxed. Hence a change in their contractions, and in the direction of those contractions, is necessarily occasioned. This alteration is such, that if the muscles act, instead of pulling the head of the bone towards the lacerated capsule, they drag it in quite a contrary direction, and thus produce a consecutive luxation.

But it is very different, when, by means of extension, the direction of the action of the muscles has been rectified. They now tend to pull the head of the bone towards the ruptured capsule, and indeed they do so with much more certainty than the surgeon, who is always ignorant of the precise situation of the opening in the capsule. On the other hand, when the extension is ill made, and the natural direction of the muscles has not been restored, the head of the bone is forced against another part of the capsule; and hence the difficulty of reduction so frequently experienced.

It follows from the preceding observations, first; that the whole skill in the treatment of luxations is to make the extension in an advantageous direction. Secondly; that, in general, what has been termed coaptation is almost always useless. Thirdly; that the reduction of a luxation does not consist in putting the head of the bone into its cavity again; but in placing the muscles in a state in which they are enabled to reduce the bone.

But it is not to be denied that there are cases where the action of the muscles being perverted, in consequence of the long existence of the dislocation, and the formation of adhesions to the surrounding parts, it becomes necessary to resort to means for forcing, as it were, the passage of the head of the bone into the glenoid cavity.

When the luxation has been reduced, the arm is to be kept motionless for a few days, lest the head of the bone should slip out of its place again. Surgeons have been accustomed to apply the spica bandage, though without the least reason, as it does no good whatsoever, because it has no effect in confining the limb. The proper practice is to keep the arm quiet, and close to the side with a roller and sling. Default himself employed the bandage described in the article FRACTURE. See *Fracture of the Clavicle*.

Method adopted by English Surgeons.—In this country, surgical practitioners always reduce dislocations of the shoulder while the patient is in a sitting posture, and, instead of imitating the French, they adhere to the ancient mode of applying the extending force to the luxated bone itself, just above the elbow. No doubt, they have been more influenced

in such practice by the authority of Mr. Pott, than by any real advantage attending the method. According to the notions of this latter gentleman, "all the force used in reducing the luxated head of a bone, be it more or less, be it by hands, towels, ligatures, or machines, ought always to be applied to the other extremity of the said bone, and as much as possible to that only." Another maxim laid down by Pott is, that in order to make use of an extending force with all possible advantage, and to excite thereby the least pain and inconvenience, it is necessary that all parts, serving to the motion of the dislocated joint, or in any degree connected with it, be put into such a state as to give the smallest possible degree of resistance.

"This (says Mr. Pott) I take to be the first and great principle by which a surgeon ought to regulate his conduct in reducing luxations. This will shew us why a knowledge of all the muscular and tendinous parts, acting upon or in connection with the articulations, is absolutely necessary for him who would do his business scientifically, with satisfaction to himself, or with ease to his patient. It will shew us that the mere position of the limb below the luxated joint, is what must either relax or make tense the parts in connection with that joint, and, consequently, that posture is more than half the business. It will shew us why sometimes the luxated os humeri slips in, as it were of its own accord, by merely changing the position of the arm, when very violent attempts, previous to this, have proved unsuccessful. It will shew us why extending the arm in a straight line, horizontally, or so as to make a right angle with the body, must in some instances render all moderate attempts fruitless. Why the method of attempting reduction by the heel in the axilla is so often successful, notwithstanding two very considerable disadvantages under which it labours; viz. part of the force being *lost in the elbow*, and the tense state of one head of the biceps cubiti. Why the tying down the fore-arm in the common ambi is wrong for the same reasons. Why the fore-arm should at all times (let the method of reduction be what it may) be bent; viz. because of the resistance of the long head of the biceps in an extended posture. Why, when the os humeri is luxated forward, or so that its head lies under the great pectoral muscle, the carrying of the extended arm backward, so as to put that muscle on the stretch, renders the reduction very difficult; and why, on the contrary, the bringing the arm forward, so as to relax the said muscle, removes that difficulty, and renders reduction easy, &c."

In our opinion, some of these observations do not shew the thing intended, quite as well as Mr. Pott seems to conceive. We do not see how *all* the parts, in connection with a joint, can be relaxed by posture. We see, it is true, how bending the elbow relaxes the biceps, but then it puts the long head of the triceps on the stretch, which may also resist the reduction. As for the extending force being *lost* in the elbow, when applied below the dislocated bone, we have endeavoured to prove the error of the supposition in our general remarks. With respect to the last part of the foregoing, we think the explanation given by Bichat, in his edition of Default's works, more correct, namely, that when the luxated head of the humerus lies forward under the pectoral muscle, carrying the elbow forwards and inwards tends to throw the head of the bone backwards and outwards, and then the muscles are enabled to act with effect in promoting the reduction.

To the truth of the ensuing remarks, delivered by Mr. Pott, we have pleasure in assenting. That in the reduction of such joints as consist of a round head moving in an acetabulum, or socket, no attempt ought to be made for replacing the said head, until it has by extension been brought forth from

from the place where it is, and nearly to a level with the said socket. This will shew us why the old method by the door, or ladder, sometimes produced a fracture of the neck of the scapula, Mr. Pott himself has seen happen. Why, if a sufficient degree of extension be not made, the towel, over the surgeon's shoulder, and under the patient's axilla, must prove an impediment rather than an assistance, by thrusling the head of the humerus under the neck of the scapula, instead of directing it into its socket. Why the common method of bending the arm, that is, the os humeri, downward, before sufficient extension has been made, prevents the very thing aimed at, by pushing the head of the bone under the scapula, which the continuation of the extension, for a few seconds only, would have carried into its proper place. When the head of the os humeri is drawn forth from the axilla, and brought to a level with the cup of the scapula, it must be a very great and very unnecessary addition of extending force, that will, or can keep it from going into it. All that the surgeon has to do, is to bring it to such a level; the muscles attached to the bone will do the rest.

A very just and important maxim, inculcated by Mr. Pott, and indeed by every judicious surgical writer of recent date, is, that whatever kind or degree of force may be found necessary for the reduction of a luxated joint, such force be employed gradually; that the lesser degree be always first tried, and that it be increased *gradatim*. See Pott's Remarks on Fractures and Dislocations, vol. i. of his works.

After adverting to a few impediments to the reduction of dislocated shoulders, we may here (not abruptly we hope) take leave of the subject, without expatiating on the methods pursued in this country, because in fact the practice of Default, as already related, differs from our's chiefly in the extension being made at the wrist. If we suppose the elbow bent, and the extending force applied just above the joint, it will be easy to follow the directions already given, with regard to the manner of making the extension, and the time and mode of altering the position of the bone during the process.

We shall conclude our account of dislocations of the shoulder, with noticing some circumstances which may tend to render the reduction difficult.

The first to which we shall request the reader's attention, is the narrowness of the lacerated opening in the capsular ligament. The practice of Default, when he had reason to suspect this kind of impediment, was to endeavour to dilate the aperture by moving the humerus very freely and forcibly in every direction, and pushing its head at the same time towards the glenoid cavity.

The luxation not being recent, may be another cause hindering the reduction, and is sometimes an insurmountable obstacle to success. The luxated head of the bone, after a time, contracts adhesions; and the surrounding cellular substance becomes condensed, and converted as it were into a new kind of capsular ligament, which confines the bone in its unnatural situation. Most surgical authors recommend us in such a case to make no endeavour to put the bone into its place again, as the attempt would, in all probability, fail, and might bring on serious consequences, by reason of the violence which must be exerted. Default once professed the same doctrine, but in the latter part of his life experience led him to a bolder practice. After being completely successful in reducing some luxations, which had existed from fifteen to twenty days, he was encouraged to attempt the reduction of others, which had happened from thirty to five and thirty days; and during the two years before his death, he had, in Bichat's presence, replaced dislocations of the shoulder after ten weeks, and even three months, when the

head of the humerus had escaped either at the inferior, or internal part of the capsule. Notwithstanding the long continued extensions which were employed, there were none of the terrible consequences induced, with which authors have intimidated the generality of practitioners. In two instances, a sudden and unaccountable emphysema of the shoulder took place, which yielded to the use of a bandage and the saturnine lotion. See *Œuvres de Default par Bichat*, tom. i. p. 377.

In cases of this kind, before the extension is begun, the bone should be freely moved about in every possible direction, in order, in the first instance, to break the adhesions, lacerate the condensed cellular substance, that serves as the accidental capsule, and thus produce, as it were, a second luxation for the purpose of curing the first. The means for extension are then to be applied as usual, with an increased number of assistants. In these cases we have seen the multiplied pulley used with advantage, though it is certainly a dangerous machine, unless in careful hands.

Frequently the first attempts are unavailing, and the luxated head of the bone continues immovable, in the midst of the most powerful efforts. The extension is then to be stopped, and the bone moved about again in all directions; every resistance is to be broken; let the arm describe a large segment of a circle in the place which it occupies; and let it be rotated on its axis. Then let extension be repeated in every direction.

For cases proving the occasional efficacy of such practice, we must refer to Default's *Œuvres Chirurg. par Bichat*, tom. i. p. 375.

In this excellent work it is observed that, supposing the attempts to fail, they are not entirely useless; for, by moving the head of the bone somewhat towards the glenoid cavity, or even just before it, they give the limb a greater freedom of motion.

A third obstacle to the reduction of all luxations arises from the power of the muscles, which power is exerted with violence in consequence of the manner in which these organs are stretched. Sometimes the resistance of the muscles, indeed, absolutely hinders the head of the bone from being at all moved, notwithstanding the extension is very considerable. In such a case, bleeding and the warm bath are to be tried, in order to bring on a temporary weakness and relaxation, during which the attempts at reduction may be made with the best prospect of success. Yet a still more certain plan is long continued unremitting extension, which is sure of fatiguing the resisting muscles, and as soon as they are worn out, the bone may easily be replaced. Default in certain cases did not succeed before the half, or even the whole of the day had been spent in keeping up the extension, by means of his apparatus for the broken clavicle, when apparatus draws outward the shoulder and into the neck. (See *Fracture of the Clavicle*.) The muscles can only support a violent contraction a certain time. To permanent extension, though moderate in degree, they cannot make long resistance, they become fatigued, they are incapable of hindering the head of the bone from being moved in the desired direction, and the reduction is accomplished.

We have seen that Mr. Pott and Default have particularly adverted to the difficulty of reduction, arising from the bone being pressed against the neck of the scapula, when the elbow was depressed, before the extension had sufficiently engaged the head. Mr. Hey has also noticed this obstacle to reduction, as follows: "the difficulty of reducing a dislocated humerus, not only arises from the resistance or compression of the muscles; but also from the resistance which is made by the pressure of the glenoid process against the

LUXATION.

neck of the humerus, when the head of the bone lies deep in the axilla beyond that process. This hindrance to reduction will be increased in proportion to the depression of the acromion; if the extension is made in a horizontal direction. For in this case the edge of the glenoid cavity pitches against the neck of the humerus, and, in some degree, prevents the head of the bone from advancing forward. In order to remove this hindrance, the head of the humerus must be lowered by elevating the arm, and the edge of the glenoid cavity raised from the neck of the humerus by repelling the acromion." Mr. Hey then states that he has now, for several years, preferred the method recommended by Mr. Bromfield, for repelling the acromion during the extension, and he insists on the propriety of bending the fore-arm, before applying the means for extension, so that the biceps may be relaxed as much as possible, and not hinder the glenoid cavity from being repelled. See *Practical Observations in Surgery*, p. 209, 300. edit. 2. A description of Bromfield's method may be found in this gentleman's *Chirurgical Observ. and Cases*, vol. i. chap. 6. p. 266.

Luxations of the Elbow-joint, or of the Fore-arm from the Humerus.—Here authors have generally described four kinds of dislocation; *viz.* backwards, forwards, outwards, and inwards; but all these cases do not occur with equal frequency, as experience proves, and the structure of the joint might enable us to anticipate.

The luxation of the bones of the fore-arm backwards are by far the most common; the dislocation of them forwards is very rare, was never observed by Default or Petit, and indeed cannot happen without a fracture of the olecranon. Luxations inwards or outwards are also not frequent, and when they do happen they must almost inevitably be incomplete, in consequence of the great extent of the articular surfaces. The frequency of luxations backwards, compared with that of lateral dislocations, is estimated in Default's works by Bichat as 10 to 1. The luxation forward being so uncommon, no comparison whatever is assigned. The coronoid process, forming only an inconsiderable curvature, cannot make any vast resistance to the ascent of the olecranon and radius, up the posterior part of the humerus. But the kind of hook which the olecranon makes, effectually hinders this process itself as well as the radius from slipping forwards in front of the humerus. Indeed, as we have already observed, a luxation in this direction may be regarded as impossible, without a fracture of the olecranon. The lateral ligaments, and the reciprocal manner in which the irregular surfaces of the articulation fit each other, are also strong obstacles to lateral dislocations. Luxations backwards are, as we have said, by far the most frequent.

In the luxation backwards, the radius and ulna may ascend more or less behind the humerus; but the coronoid process of the ulna is always carried above the articular pulley, and is found lodged in the cavity destined to receive the olecranon. The head of the radius is placed behind and above the external condyle of the humerus. The annular ligament, which confines the superior extremity of the radius to the ulna, may be lacerated; in which case, even when the bones are reduced, it is difficult to keep them in their proper places, as the radius tends constantly to separate from the ulna.

This luxation always takes place from a fall on the hand; for, when we are falling, we are led by a mechanical instinct to bring our hands forwards to protect the body. If in this case the superior extremity, instead of resting vertically on the ground, be placed obliquely with the hand nearly in a state of supination, the repulsion which it receives from the ground will cause the two bones of the fore-arm

to ascend behind the humerus, whilst the weight of the body pressing on the humerus, directed obliquely downwards, forces its extremity to pass down before the coronoid process of the ulna.

The fore-arm, in this luxation, is in a state of half-flexion, and every attempt to extend it occasions acute pain. The situation of the olecranon, with respect to the condyles of the humerus, is changed. The olecranon, which in the natural state is placed on a level with the external condyle, which is itself situated lower than the internal, is even higher than the latter.

This luxation may be mistaken for a fracture of the olecranon, of the head of the radius, or even of the inferior extremity of the humerus. Such a mistake is attended with very bad consequences; for if the reduction be not effected before the end of fifteen or twenty days, it is often impossible to accomplish it afterwards. The swelling, which supervenes in twenty-four hours after the accident, renders a diagnosis more difficult; but the olecranon and internal condyle are never so obscured, that the distance between them cannot be found to be increased, though Boyer makes a contrary assertion. It is true, that the rubbing of the coronoid process and olecranon against the humerus, may cause a grating noise, similar to that of a fracture: and some attention is certainly requisite to establish a diagnosis between a fracture of the head of the radius, and a dislocation of the fore-arm backwards.

The following method of reducing the case is advised by Boyer:—The patient being firmly seated, an assistant is to take hold of the middle part of the humerus, and make the counter-extension, while another assistant makes extension at the inferior part of the fore-arm. The surgeon, seated on the outside, grasps the elbow with his two hands, by applying the fore-fingers of each to the anterior part of the humerus, and the thumbs to the posterior, with which he presses on the olecranon, in a direction downwards and forwards. This method will be in general successful. If the strength of the patient, or the long continuance of the luxation, render it necessary to employ a greater force, a fillet is to be applied on the wrist, to make extension, and a cushion is to be placed in the axilla, and the arm and trunk fixed, as is done in cases of luxation of the humerus.

A bandage may afterwards be applied, in the form of a figure of 8, and the arm is to be kept in a sling. The laceration which always takes place, is always followed by more or less swelling, which is to be combated by antiphlogistic means.

At the end of seven or eight days, when the inflammatory symptoms are nearly gone, the articulation is to be gently moved, and the motion is to be increased every day, in order to prevent an anchylosis, to which there is a great tendency.

In this luxation, the annular ligament which confines the head of the radius to the extremity of the ulna, is sometimes torn, and the radius passes before the ulna. In such cases, pronation and supination are difficult and painful, though the principal luxation has been reduced. The head of the radius may be easily replaced, by pressing it from before backwards, and it is to be kept in its place by a compress, applied to the superior and external part of the fore-arm. The bandage and compresses are to be taken off every two or three days, and re-applied. This is necessary, on account of the necessity of moving the articulation to prevent an anchylosis.

If the luxation be not soon reduced, it becomes irreducible; the heads of the radius and ulna grow to the back part of the humerus, and the patient can neither bend nor extend

tend his arm. However, in some cases, especially in young persons, some motion is acquired in time; the heads of the radius and ulna making in the humerus cavities, in which they perform some motions, but always imperfectly.

The luxation forward should be treated as a fracture of the olecranon, with which it would be inevitably accompanied. It may be necessary, on account of the great injury done to the soft parts, to bleed the patient copiously, and put him on an antiphlogistic regimen.

As to the lateral luxations, either inwards or outwards, they are always incomplete, and easily discovered. They are reduced by drawing the humerus and fore-arm in contrary directions, and at the same time pushing the extremity of the humerus, and the two bones of the fore arm in opposite directions.

These luxations cannot be produced without considerable violence; but when the bones are reduced, they are easily kept in their place. It will be sufficient to pass a roller round the part, to put the fore-arm in a middle state, neither much bent nor extended, and to support it in a sling. But much inflammation is to be expected from the injury done to the soft parts. In order to prevent it, or at least mitigate it, the patient is to be bled two or three times, and put on a low diet, and the articulation is to be covered with the lotio aq. litharg. acet. It is scarcely necessary to repeat, that the arm is to be moved as soon as the state of the soft parts will admit of it.

The dislocation of the fore-arm backward, is said to occur ten times as frequently as lateral luxations; and those forward are so rare, that no comparison whatever can be drawn. *Oeuvres Chir. de Default, tom. i.*

Lateral luxations have been divided into *complete*, that is, when the articular surfaces have entirely lost their state of reciprocal contact; and into *incomplete*, that is, when only one bone, or a part of it, is thrown off the humerus. But what cause can operate with sufficient force to produce the first occurrence? The mischief would also be so great, were such a case to happen, that amputation would most likely be requisite.

The incomplete lateral luxation may be produced by a blow, which drives the upper part of the fore-arm violently outward, or inward. A footman, says Petit, in falling from a coach, had his arm entangled in the spokes of a wheel, and a dislocation outward was the consequence. Another man luxated his fore-arm inward, by falling from his horse and driving his arm against an uneven place.

When the ulna is pushed into the situation of the radius, the space between the olecranon and internal condyle is much greater than is natural. These points of bone are always very distinguishable, let the joint be ever so much swollen; and hence, the information to be derived from an examination of them, may be obtained in every case, without exception. Also, when the ulna is pushed into the place of the radius, the latter bone cannot be easily rotated, nor can the fore-arm be bent and extended in a perfect manner.

The dislocation inward must be very uncommon, as the form of the bones is almost an insurmountable obstacle to such an accident. It may happen, however, as the authority of Petit confirms.

All recent dislocations of the elbow are very easily reduced, and as easily maintained so; for the reciprocal manner in which the articular surfaces receive each other, and their mutual eminences and cavities, will not readily allow the bones to become displaced again.

The application of a bandage in the form of a figure of 8,

and supporting the arm in a sling, are proper in all these cases.

Luxation of the Radius from the Ulna.—The majority of authors, who have written on dislocations of the fore-arm, have not separately considered those of the radius. Some detached observations, on luxations of its superior extremity, are to be found here and there; a subject which Duverney alone has fully treated of. The dislocations of its lower end, which are more frequent, and easy of occurrence, have almost escaped the notice of French, and also English writers. At present, cases of this sort have been so numerously collected, that a particular account of them may be offered.

Difference of Structure, between the two Joints of the Radius with the Ulna.—The radius, the moveable agent of pronation and supination, rolls round the ulna, which forms its immoveable support, by means of two articular surfaces; one above, highly convex, broad internally, narrow outwardly, and corresponding to the little sigmoid cavity of the ulna, in which it is lodged; the other below, concave, semi-circular, and adapted to receive the convex edge of the ulna. Hence there are two joints, differing in their motions, articular surfaces, and ligaments. By ascertaining such differences, we shall be enabled to find out those which exist between the luxations of the upper and lower head of the radius.

Above, the radius, in pronation and supination, only moves on its own axis; below, it rolls round the axis of the ulna. Here, being more distant from the centre, its motions must be both more extensive and powerful than they are above. The head of the radius, turning on its own axis in the annular ligament, cannot dislodge in any direction. On the contrary, below, the radius, in performing pronation, stretches the posterior part of the capsule, and presses it against the immoveable head of the ulna, which is apt to be pushed through, if the motion be forced. A similar event, in a contrary sense, takes place in supination. The front part of the capsule, being rendered tense, may now be lacerated.

Add to this disposition, the difference of strength between the ligaments of the two joints. Delicate and yielding below; thick and firm above; their difference is very great. The upper head of the radius, supported on the smaller immoveable articular surface of the ulna, is protected from dislocation in most of its motions. On the contrary, its lower end, carrying along with it in its motions the bones of the carpus which it supports, cannot itself derive any solid stability from them.

Differences of Luxations of the Radius.—From what has been said, the following conclusions may be drawn; 1. that with more causes of luxation, the lower articulation of the radius has less means of resistance; and, that under the triple consideration of motions, ligaments tying the articular surfaces together, and the relations of these surfaces to each other, this joint must be very subject to dislocation. 2. That, for opposite reasons, the upper joint cannot be very subject to such an accident.

Indeed what could be the cause producing it in this situation? Can it arise from a violent pronation, or supination? The lower joint being the weakest would give way the first, and however forcible any motion of this kind might be, the upper head of the radius would only be rotated on its own axis. How then can this part be dislocated without being pushed forward or backward? All the muscular and ligamentous support of the joint must be broken; and the muscles and ligaments are too strong to admit of this, and the motion itself too feeble. Can the accident originate from

any impulse on the radius, from below upward? The immoveable resisting end of the humerus would then prevent the radius from quitting the capsular ligament. Can the accident arise from a violent extension or flexion of the forearm? Here, the whole force operating on the ulna, the radius scarcely feels the impulse.

Hence, accidental dislocations of the radius, suddenly produced by an external cause, must, if they ever happen, be exceedingly uncommon at its upper end. This is not the case with respect to such dislocations which occur slowly at this joint, especially in children, in whom the ligaments become lax in consequence of repeated efforts. With this kind of case, we have here nothing to do.

Experience sometimes seems to militate against the above reflections. Duverney quotes some instances of dislocations of the radius, suddenly produced by external causes. Some other practitioners mention similar examples. But, in their examinations, have these men paid all due attention? An analogous case has been transmitted to the French Academy of Surgery, by one of its fellows; but doubts have arisen concerning its reality, and there are too few facts for, and too much presumptive evidence against, the truth of such cases to believe their existence. Desault himself rejected their reality.

Luxation of the lower End of the Radius.—The causes are the same as those of all analogous cases. 1. Violent action of the pronator and supinator muscles. This is, doubtless, a very unusual cause, for Desault never knew an instance of it. 2. External force, moving the radius violently into a state of pronation, and rupturing the back part of the capsule; or into a state of supination, and breaking the front part of the capsular ligament.

Hence, there are two kinds of dislocation; one forward, the other backward. The first is very frequent; the second is much less so. The latter case never presented itself to Desault but once, in the dead body of a man who had both his arms dislocated, and no particulars could be learnt. The other case occurred very often in the practice of this eminent surgeon. Five examples have been published. Doubtless, this difference is owing to all the principal motions of the radius being in the prone direction.

This observation is confirmed by the fact, that the lower joint of the radius, in the dead subject, may be dislocated as easily by a supine, as a prone motion of this bone.

The symptoms of the luxation forward are: 1. Constant pronation of the forearm. 2. An inability to perform supination, and great pain on this being attempted. 3. An unusual projection at the back of the joint, in consequence of the protrusion of the little head of the ulna through the capsule. 4. The position of the radius is more forward than natural. 5. Constant adduction of the thumb, which also is almost always extended. 6. A half-bent state of the forearm, and very often of the fingers. Thus, indeed, is the position which the forearm usually assumes in all affections of its bones, and, in the present instance, the posture cannot be changed without considerable pain. 7. More or less swelling around the joint. This sometimes comes on immediately after the accident, but always afterwards, if the reduction should remain unaccomplished. The condition of the joint may thus be obscured, and the accident mistaken for a sprain; as Desault often observed to have occurred with surgeons, who had been called to these accidents before him. The serious consequence of this mistake is, that no attempt at reduction is made, and the articular surfaces having time to contract adhesions, the disorder is frequently rendered irremediable.

A luxation of the radius backward is characterized by

symptoms the reverse of those above-mentioned. They are a violent supination of the limb; inability to put it prone; pain on making the attempt; a tumour in front of the forearm formed by the head of the ulna; a projection backward of the large head of the radius; and abduction of the thumb.

Reduction.—When the dislocation is forward, an assistant is to take hold of the elbow, raising the arm a little from the body; another is to take hold of the hand and fingers.

The surgeon is to take hold of the end of the forearm with both his hands; one applied to the inside, the other to the outside, in such a manner, that the two thumbs meet each other before, between the ulna and radius, while the fingers are applied behind. He is then to endeavour to separate the two bones from each other, pushing the radius backward and outward, while the ulna is held in its proper place. At the same time the assistant, holding the hand, should try to bring it into a state of supination, and consequently the radius, which is its support. Thus pushed, in the direction opposite that of the dislocation, by two powers, the radius is moved outward, and the ulna returns into the opening of the capsule, and into the sigmoid cavity.

If chance should present a dislocation of the radius backward, the same kind of proceeding, executed in the opposite direction, would serve to accomplish the reduction.

Luxations of the Wrist.—The carpal bones may be luxated from the lower ends of the radius and ulna forwards, backwards, inwards, or outwards. The two first cases, especially the one backwards, are the most frequent. The dislocation backwards is rendered easy by the direction of the convex articular surfaces of the scaphoid, semilunar, and pyramidal bones, which sloping more backwards than forwards, must make them more disposed to slip in this direction than any other. The accident may be caused by a fall on the back of the hand, while much bent; in which event the first row of the carpal bones slide backwards into the oblong cavity of the radius, lacerate the posterior ligament, and form an eminence behind the lower ends of the bones of the forearm. This prominence, the depression in front of the wrist, and the extraordinary flexion of the hand, which cannot be extended, are the characteristic signs of this kind of dislocation.

The dislocation forwards generally arises from a fall on the palm, the fingers being extended, and more force operating on the lower than upper part of the palm. The luxation is seldom complete; and the hand remains painfully extended. The great many tendons, which run before the wrist, and the annular ligament being pushed forward, the prominence formed by the carpal bones, in front of the ends of the radius and ulna, is not easily detected, and the case may be mistaken for a sprain.

Dislocations inwards, or outwards, are never complete. The projection of the carpal bones at the inner or outer side of the joint, and the distortion of the hand, make such cases sufficiently evident.

All dislocations of the wrist are very easy of reduction. For this purpose, gentle extension must be made, while the two surfaces of the joint are made to slide on each other in a direction contrary to what they took when the accident occurred.

Dislocations of the wrist are always attended with a great deal of spraining of numerous tendons and laceration of ligaments, and consequently considerable swelling generally follows, and the patient is a long time in regaining the perfect use of the joint. To relieve the symptoms as much as possible, the best plan is to keep the hand and wrist continually covered with linen wet with the saturnine lotion, and

to put the fore-arm and hand in splints, as in the case of a fracture. (See FRACTURE.) The arm must also be kept perfectly at rest in a sling.

When the ruptured ligaments have united, the use of liniments will tend to remove the remaining stiffness and weaknesses of the joint.

Luxations of the Bones of the Carpus and Metacarpus.—A dislocation of the carpal bones from each other seems almost impossible. The os magnum, however, has been known to be luxated from the deep cavity formed for it by the trapezoides and semilunare, in consequence of too great a flexion of the bones of the first phalanx on those of the second, and it forms a tumour on the back of the hand. Chopart. Boyer. Richerand.

The metacarpal bones are never luxated from each other. The first one is sometimes, though very rarely, pushed off the trapezium.

Luxations of the Fingers.—The first phalanges may be dislocated backwards off the heads of the metacarpal bones. A luxation forwards would be very difficult, if not impossible, because the articular surfaces of the metacarpal bones extend a good way forwards, and the palm of the hand makes resistance to such an accident. The first phalanges of the thumb and little finger can alone be dislocated inwards; and the first phalanx of the thumb is alone subject to be luxated outwards. This phalanx is also most liable to dislocations backwards, behind the head of the first metacarpal bone, in which case it remains extended, while the second is bent.

These dislocations should be speedily reduced; for, after eight or ten days, they become irreducible. In a luxation of the first bone of the thumb, which was too old to be reduced, Default proposed cutting down to the head of the bone, and pushing it into its place with a spatula. Dislocations of the thumb and little finger inwards, that of the thumb outwards, and luxations of the first phalanges of the other fingers backwards, are all reduced by making extension on the lower end of the affected thumb, or finger. The first and second phalanges may also be dislocated backwards.

After the reduction, the thumb or finger affected should be rolled with tape, and incased, and supported in plaster-board, till the lacerated ligaments have united; taking care to keep the hand and fore-arm quietly in a sling.

Luxations of the Femur, or Thigh-bone, at the Hip.—These dislocations may take place upwards and outwards on the external surface of the os ilium; upwards and forwards on the body of the os pubis; downwards and inwards on the foramen ovale; and downwards and outwards on the os ischium.

The luxation upwards and outwards, and that downwards and inwards, are the most frequent, and it is not easy to say which of these two cases happens most often. It is to be understood, however, that dislocations of the hip are far less common than those of the shoulder. We have seen only three cases of the first description; but, at least, from fifteen to twenty dislocations of the shoulder. Mr. Hey informs us, that seven instances of the latter accident, and three of the former, are all that have occurred in his practice. (Pract. Obs. p. 314. edit. 2.) The following account of luxations of the thigh-bone at the hip is from Boyer's work on the Diseases of the Bones, transl. by Farrell.

No anatomical reason can be given for the frequency of the dislocation upwards and outwards; the edge of the acetabulum projects more at the superior and exterior parts than at any other; the orbicular ligament, which is very thick at this place, and the interior ligament of the articulation,

which must be previously ruptured, oppose the dislocation in this direction. There is little, on the contrary, to oppose the luxation downwards on the foramen ovale. The inferior and internal part of the circumference of the cavity, the place by which the bone escapes in this species of luxation, presents a deep notch formed into a hole by a ligament, under which the wifils of the articulation enter. The orbicular ligament is thinner here than at any other place; the motion of abduction, in which this luxation takes place, is more extensive than that of adduction; and lastly, the round ligament within the articulation does not oppose it, as it may take place without its being ruptured.

Luxation upwards and forwards is very rare; that downwards and backwards is still more so; and, perhaps, as shall be observed farther on, never occurs but secondarily.

When, by a fall from a place more or less elevated, on the sides of the feet, or on the knee, the thigh is pushed forwards and inwards, the head of the femur, forced towards the superior and external part of the acetabulum, breaks the internal and orbicular ligaments, escapes through the laceration in the latter, and ascends on the internal face of the os ilium; but as the part of the os ilium immediately above and at the external side of the cavity is very convex, the head of the femur soon abandons its first position, and slides backwards and upwards into the external fossa of the os ilium, following the inclination of the plane towards this fossa, and obeying the action of the gluteal muscles, which draws it in this direction. The head of the femur, in ascending thus on the external face of the os ilium, pushes upwards the glutæus minimus, which forms a sort of cap for it; and the glutæus maximus and medius are relaxed by the approximation of the points into which they are inserted. The pyriformis is nearly in its natural state, the gemini, obturators, and quadratus femoris, are a little elongated. The psoas magnus and iliacus internus are relaxed, as are also the other muscles inserted into the trochanter minor. If to this description it be added, that the orbicular ligament, torn at its superior part, is stretched over the acetabulum, and covers it, an exact idea may be formed of the change occasioned in the surrounding parts by this luxation of the femur.

The affected thigh is shorter than the sound one; it is a little bent, and carried inwards. The knee inclines more forwards and inwards than the opposite one; the leg and thigh are turned inward, and the foot points in this direction. The trochanter major is brought nearer the anterior and superior spinous process of the os ilium, and is at the same time elevated and carried a little forward; the latter circumstance may be considered as the necessary consequence of the rotation inwards of the thigh. The natural length of the limb cannot be restored without reducing the luxation; the foot cannot be turned outwards, and any attempt to do so causes pain; but the inclination of the foot inwards may be increased. If the patient endeavours to walk, he extends the foot to put the top of it on the ground; and though the heel is raised, he is still lame; for the diseased limb remains always shorter than the other, and the pain occasioned by the attempt to walk renders progression still more difficult.

Luxation of the femur upwards and outwards has nothing in common with the fracture of the neck of this bone but the shortness of the limb. The easy rotation of the member outwards and inwards, &c. &c. preclude all possibility of confounding them, unless the surgeon be remarkably inattentive.

It is difficult to assign the cause of the foot and remainder of the limb being turned inwards in this luxation. It may be

LUXATION.

be established as a general rule, that luxated members always take a direction determined by the elongation of the muscles of the side opposite that to which the luxated bone is carried: thus, in luxation of the arm downwards and inwards, the deltoides and infraspinatus muscles, lengthened by the separation of their points of insertion, move the elbow out from the body, and give the arm an oblique direction. In this case, the obturator, gemini, and quadratus femoris, being elongated, the point of the foot ought to be turned outwards. This phenomenon depends perhaps on the external portion of the orbicular ligament which comes from the anterior and inferior spine of the os ilium; this portion, which is very thick, being elongated in the luxation outwards, draws the great trochanter forwards, and consequently turns towards the entire limb.

The difficulty of reducing luxations of the thigh, from the strength and number of its muscles, renders every dislocation of which it is susceptible very distressing. The laceration and injury done to the soft parts are nearly as considerable as in dislocation of the ginglymoidal articulations.

To effect the reduction, the patient is extended on a table firmly fixed, and covered with a mattress, which is to be tied to it; a sheet, folded longitudinally, is applied to the groin of the sound side, in order to make counter-extension. The middle part is applied against the superior and internal part of the thigh, and the two ends passed before and behind the pelvis, cross on the hip, and are held by a sufficient number of assistants. By this means the trunk is fixed, but there is nothing to prevent the pelvis from yielding to the extending force. To answer this purpose, another sheet, folded in a similar manner, is placed transversely on the spine of the os ilium, and its ends are brought horizontally before and behind the abdomen towards the hip of the opposite side, where they are held by assistants. This apparatus, similar to that placed on the point of the shoulder in a luxation of the arm, answers the same purposes, as it presses only on the superior part of the glutæus maximus and medius, and does not stimulate them to contract. The extending force is to be applied to the inferior part of the leg, in order to have it as far as possible from the parts which resist the return of the head of the femur. The number of assistants for making extension and counter-extension is to be proportioned to the exigencies of the circumstances and the power of muscles. The surgeon, placed at the external side of the limb, presses on the great trochanter, and when the head of the bone has been brought on a level with the acetabulum, he endeavours to force it into it.

In this country, as we have previously explained, surgeons generally apply the extension to the dislocated bone itself, just above the knee. The disappearance of all the symptoms, and especially the noise made by the head of the femur on re-entering its cavity, indicate the success of the operation. This success is seldom obtained without having previously made several fruitless endeavours, whether from not employing sufficient force to make extension and counter-extension, or from a spasmodic contraction of the muscles obstinately resisting the reduction.

When the bone is reduced, it is prevented from leaving its place by bringing the thighs together by means of a bandage passed below the knees. In the generality of cases, it will be advisable to take some blood from the patient, and confine him for a few days after the accident to a very low diet; and in all cases the hip is to be covered with emollient and resorbent applications, which may be kept on by means of the spica bandage for the groin. This bandage is well

adapted to this use, but is not at all fit for keeping the luxated bone in its proper place, as its action is made too near the centre of motion. The patient should be particularly directed not to walk too soon, nor at any time to fatigue too much the affected joint.

Luxation of the thigh downwards and inwards, or into the foramen ovale, is nearly as frequent as that just described; it is favoured, as we have said, by the great extent of the motion of abduction of the thigh; by the notch at the inferior and internal part of the acetabulum, by the weakness of the orbicular ligament at this side; and lastly, by the situation of the round ligament, the rupture of which is not a necessary consequence of it. It is occasioned by a fall on the feet or knees considerably separated from one another. The head of the femur slides from without inwards on the bottom of the acetabulum, and comes against the inferior and internal portion of the orbicular ligament, which it lacerates, and passes on to the foramen ovale between the ligament and the obturator externus.

In this species of luxation of the femur, the state of the soft parts surrounding the articulation is as follows: the glutæi, gemini, obturatores, quadratus femoris, psoas magnus, and iliacus internus, are elongated by the separation of their points of insertion. The rotation of the limb outwards is produced by the elongation of these muscles. The adductors, elongated, form at the interior part of the thigh a tense cord, which is felt from the pubis to below the middle of the thigh.

The affected thigh is longer than the sound one; the head of the femur being placed lower than the acetabulum, the great trochanter is removed to a greater distance from the anterior and superior spinous process of the os ilium, and the thigh is flattened in consequence of the elongation of the muscles. The adductors, extended obliquely from the pubis to the femur, form a cord which elevates the skin of the internal part of the thigh. A hard round tumour is felt at the inner and superior part of the thigh, formed by the head of the femur, which elevates the soft parts situated before the foramen ovale. The leg is slightly bent; the knee and foot, turned outwards, cannot be brought back to their proper direction. If the patient attempt to walk a few steps, he makes a semicircular motion with the foot, and places at once the entire sole on the ground; and though he keep the knee bent, still the limb is too long, and occasions lameness. The mode of progression of persons whose thigh is luxated in this direction may be compared to that of a mower: the elongated extremity, like the leg which the mower keeps forwards, describes a semicircular motion outwards.

All these symptoms, taken together, form a combination too striking to admit of error in our diagnosis, or to allow us to confound this luxation with any other, or even with fracture of the neck of the femur.

The prognosis is somewhat less unfavourable in this than in luxation upwards and outwards. The muscles, which might oppose the reduction, being all elongated by the very circumstance of the luxation itself, render the reduction easier; besides, the confusion of the soft parts is less considerable, and the round ligament is stretched, but not broken. It is reduced in the same manner as the other, except that the extension is to be made at first downwards and outwards, before bringing the limb to its natural direction.

Luxation upwards and forwards is much rarer than the preceding, and more than one practitioner has described it rather as possible than as having absolutely taken place. It has been also called luxation on the pubis, though it may be reasonably presumed that the head of the femur is removed

LUXATION.

moved so far from the acetabulum but in very few cases, and that it only advances near the ilio-pectineal eminence. Default met with a luxation of this kind in a porter of the flour-market; his foot slipped, and the leg and thigh were carried backwards, whilst a heavy burden was placed on his shoulders. His body was bent backwards, and the head of the femur, directed forwards and upwards, burst its capsule and triangular ligament, and passed under the crural arch into the fold of the groin, where it was easily felt through the integuments.

The whole extremity is turned outwards in this luxation; it is also shortened. The great trochanter, brought nearer the anterior and superior spinous process of the os ilium, is placed before that eminence; that part into which the psoas and iliacus muscles are inserted is raised up, and a tumour is formed by the head of the femur in the fold of the groin, which compresses more or less the crural nerves placed at the external side of the vessels of this name, and occasions dull pains, with numbness and even paralysis, when the contusion has been very great; the knee, turned outwards, is also carried backwards. This symptom is particularly remarkable shortly after the accident has taken place; for if the dislocation has continued some days, the thigh may reassume its natural direction, and perform even gentle rotatory motions inwards, the direction outwards still continuing. It is proper to remark, with respect to the tumour formed by the head of the femur in the groin, that the psoas and iliacus muscles may, in fractures of the femur immediately under the little trochanter, bring forwards the superior portion of this bone, cause it to project in the groin, and form an eminence there which might impose on us, if we were not apprized of the possibility of such an event taking place.

This luxation is particularly dangerous, as it requires a combination of violent efforts to produce it, and as it necessarily must be accompanied with great contusion and lacerations. Nevertheless, in the case treated by Default, the reduction, though difficult, was not followed by any serious accident; and the patient, at the end of fifteen days, had almost entirely recovered the strength and use of his limb.

The process for reducing it does not differ from that pointed out for the others.

Luxation of the femur downwards and backwards may, like that of the humerus inwards and forwards, be either primary or secondary. It is primary, when, in consequence of some effort, the head of the femur is forced from the acetabulum at its inferior and posterior part, and is placed at the junction of the os ilium and ischium; it is secondary, when it succeeds to the luxation upwards and outwards, the head of the femur, which was placed at first in the external iliac fossa sliding downwards and backwards, its passage in this direction being favoured by the bending of the thigh on the pelvis.

In these two cases, the head of the femur rests against that part of the ossa innominata where the os ilium and ischium join. The muscles which cover the posterior part of the articulation, such as the pyriformis, gemini, obturators, and quadratus femoris, are raised up and stretched; the psoas magnus and iliacus internus are in a great state of tension, and this explains the turning of the limb outwards. When this luxation is primary, the extremity is lengthened; a hard tumour is felt at the posterior and inferior part of the thigh; the great trochanter, by descending, is removed farther from the spine of the os ilium, and the knee and sole of the foot are turned outwards; but if it be secondary, the thigh is much bent against the pelvis; the knee and sole of the foot are turned inwards, because the primary luxation has been upwards and outwards. Secondary lux-

ation in this direction is much more frequent than the primary; in reducing it the same rules are to be observed as in other species of luxations.

Whatever may be the species of luxation, we should always be certain that it is perfectly reduced before leaving the patient. To ascertain this, we ought to move the thigh in various directions, taking care at the same time to omit that motion which might reproduce the luxation.

When a luxation of the femur upwards and outwards has not been reduced, the thigh remains short, and becomes shorter every day, until the head of the femur has made for itself a kind of articular cavity in the surface of the external iliac fossa. The acetabulum lessens in size, or is entirely obliterated. The gluteus minimus is emaciated, and serves as an orbicular ligament to the new articulation. The head of the femur loses its spherical figure, is forced backwards, and its neck becomes shorter; the person is lame, and walks on the point of the foot. If the luxation is downwards and inwards, the foramen ovale becomes the new articulating cavity; the obturator externus, raised and pushed inwards by the head of the femur, becomes emaciated and ligamentous, and it and the gluteus minimus even sometimes ossify. The lameness arises in this case from the excess of length of the diseased limb, which always diminishes in size, in consequence of the muscles not being sufficiently exercised, or their action being impeded.

Luxations of the Patella, or Knee-pan.—It is impossible for the patella to be dislocated downwards without the tendon of the extensor muscles of the leg being first ruptured; nor upwards, unless the ligament of the patella is broken. In this last case the extensor muscles may draw the bone more or less upwards towards the groin.

Dislocations inwards, or outwards, may happen without other mischief. They occur when the patella is violently pushed in one of these directions. According to Boyer, great relaxation of the inferior ligament of the patella may create a predisposition to the accident. Such, says he, was the case of the young man, whose patellæ were luxated outwards by the slightest motion of the knees, as related by Hard in the Journ. de Méd.

The dislocation outwards is the most common. This may depend partly on the internal edge of the patella projecting more than the external one, and, therefore, being more exposed to violence; and partly, on the outer condyle of the thigh-bone allowing the patella to slip over it with facility.

Boyer observes, that the external condyle of the femur, which is naturally more eminent anteriorly than the inner one, may be depressed, and this depression, from whatever cause it may proceed, favours the dislocation outwards. He tells us that he has seen, among the military convicts, three cases of luxation of the left patella outwards from such a cause. In these three individuals the patella was placed at the outside of the condyle, though not altogether away from it. The anterior surface of the bone was turned outwards; the posterior one inwards; the internal edge was placed anteriorly, and projected under the skin, while the external edge was directed backwards. In all these instances the luxation had taken place during infancy. By relaxing the extensors of the leg, and bending the thigh, the patella could easily be replaced; but unless confined in its proper situation, it was soon dislocated again.

Another case is recorded by the same writer, where a luxation of the patella outwards followed a gunshot-wound in the vicinity of the knee.

Luxations outwards, produced by external violence, are rarely complete, as such an accident could only arise from a degree

LUXATION.

degree of force that is hardly ever exerted. The dislocation is much promoted by the knee being, at the time of the blow, in a moderate state of flexion, as the extensor muscles of the leg and ligament of the patella are then relaxed, and the inner edge of the patella very prominent, so as to be exposed to the action of external force.

In luxations of the patella outwards, the patient experiences severe pain, and cannot bend his knee. The latter joint is deformed; the pulley of the condyles of the femur may be felt through the skin; the patella forms a tumour in front of the external condyle; the anterior surface of the knee-pan is become the external one, while the posterior surface is now internal. The internal edge is turned more forwards than inwards, and the external one is now turned almost quite backwards.

The symptoms of a luxation inwards are very analogous to those of the preceding case, allowance being made for the difference of situation and the relation of parts to each other.

In every case of dislocated patella, the reduction should be effected as soon as possible. The patient is to be laid on a bed, with his leg extended and thigh bent. In this position the extensor muscles and their tendon, and the ligament of the patella, are relaxed, and the latter bone may easily be put back into its proper situation by pressure.

The inflammatory swelling, which usually affects after an accident of this nature, is to be subdued by general and topical bleeding, rest, and the saturnine lotions. After the swelling and inflammation are diminished, the joint should be gently bent and extended every day, and rubbed with the linimentum fapon. comp.

Luxations of the Knee.—The tibia, at its articulation with the condyles of the femur, may be luxated either backwards, forwards, or to either side.

A complete luxation of the knee is an exceedingly uncommon circumstance, and could not happen without a total laceration of all the numerous ligaments and tendons which strengthen the joint. For the production of such mischief, we must suppose the operation of a degree of violence that hardly ever takes place, putting out of the question the tearing away of limbs by cannon-balls. Even incomplete luxations, inwards or outwards, are very rare, so much are these accidents opposed by the extent of the articular surfaces, and the strength of the ligaments and tendons. Dislocations forwards or backwards are still more uncommon, in consequence of the manner in which the patella and crucial ligament resist their occurrence. However, when the leg is fixed, and the body and thigh are forced onwards, the tibia may be partly forced away from the lower end of the femur to one side or another. The accident implies the operation of considerable violence. The deformity makes the nature of the case very manifest. The reduction is easily accomplished by pushing the heads of the bones in opposite directions, while the articular surfaces are a little separated by moderate extension of the limb. After the reduction, the main business of the surgeon is to avert and diminish inflammation of the joint by cold washes, leeches, venesection, opening medicines, low diet, perfect rest, &c.

Luxations of the Ankle Joint.—The foot may be luxated inwards, or outwards; or forwards, or backwards; and the dislocation in any of these directions may be complete or incomplete. Luxations inwards or outwards, are the most frequent. The former, however, are more common than the latter. As the internal malleolus does not descend so far as the external, the astragalus has a less space to describe from without inwards, than in the contrary direction. The dislocation inwards is occasioned by a violent abduction of

the foot, and is characterized by the sole being turned outwards, and the back of the foot inwards, by the pain and inability of moving the foot; and, lastly, by the projection made by the astragalus below the internal malleolus.

The luxation outwards is attended with an impossibility of moving the foot; the sole is turned inwards and the back of the foot outwards; and the astragalus projects below the external malleolus.

All luxations of the foot should be reduced as quickly as possible. One assistant is to make the counter-extension by fixing the leg, and, while another draws the foot, the surgeon is to push the latter part in a direction contrary to that in which it is luxated. Nothing facilitates the reduction of dislocations of the ankle so materially as relaxing the powerful muscles of the calf of the leg, by bending the knee and extending the foot.

When the reduction has been accomplished, the limb is to be put in splints, just as if the case were a fracture of the leg, (see FRACTURE,) and the antiphlogistic treatment is indicated for the prevention of violent inflammation.

These cases, in former days, generally ended so badly, that J. L. Petit recommends amputation never to be delayed more than twenty-four hours after the accident. More modern experience, however, has proved the general possibility of curing dislocations of the ankle, and this even when the case is compound, that is, attended with a wound communicating with the injured point.

A fracture of the fibula near its lower end is a frequent complication of a luxation of the foot inwards. That bone, therefore, should always be carefully examined in the latter case.

Luxations forwards and backwards, less frequent than those described, are however sometimes met with. The first is occasioned by a fall backwards while the foot is fixed to the ground; the second by a fall on the feet, with the body inclined forwards and the leg much bent. The luxation forwards is more difficultly produced than that backwards, on account of the articular pulley of the astragalus, which inclines towards the posterior side, being permitted to slide much on the tibia without abandoning it in the extension of the foot. When the extension is carried too far, luxation forwards is produced.

In the luxation backwards, the external and posterior ligaments and the posterior part of the capsule are torn; in that forwards the anterior and external ligaments, the anterior fibres of the internal lateral ligament, and the anterior part of the capsule, are torn. The symptoms of the first species are, a diminution of length in that part of the foot between the lower part of the leg and the anterior extremity of the toes, elongation of the heel, tension of the tendo Achillis, and relaxation of the extensors of the toes. It is impossible either to bend or extend the foot; this symptom distinguishes luxation from sprain, in which the foot may be moved, though not without pain, however high the inflammation may be.

Contrary symptoms accompany the luxation forwards: the foot is lengthened, the heel is shortened, and the foot, much extended, cannot be bent, &c.

The reduction of both is easily effected, after which it will be necessary to put the limb in splints, and lay it in the bent posture.

The very thick and short ligamentous substance which unites the astragalus to the os calcis, binds them so strongly together, that they follow one another in their motions and form, as it were but one bone. Hence they are never completely separated, even in the most desperate cases of luxation of the foot; but one or both of them may be luxated

from the scaphoides and cuboides. The transverse direction of the articulation formed by these four bones, suggested to Chopart the ingenious idea of amputating only a part of the foot. But these luxations, less dangerous than the others, can be occasioned only by a violent effort in which the anterior part of the foot is fixed, as happened in the two cases related by J. L. Petit, the foot being fastened in an iron grate, whilst the body was drawn backwards. The astragalus and os calcis may, under these circumstances, be luxated, but particularly the former, the head of which slides from below upwards, in the cavity of the posterior face of the scaphoides, and forms a tumour on the back of the foot. The inflammatory swelling renders it often difficult to ascertain this luxation. It is not easily reduced, even shortly after it has taken place. Boyer failed in a case of this kind in which the head of the astragalus was luxated upwards and inwards by a fall from a horse; but in some time the person felt no inconvenience from the affection, he could walk without pain or lameness, and nothing remained but the deformity occasioned by the tumour.

The other bones of the tarsus and metatarsus are too strongly tied together to admit of luxation. The phalanges of the toes cannot be luxated by external violence, on account of their shortness. However, the possibility of luxation of the first phalanx of the great toe from the first bone of the metatarsus may be easily conceived. See Boyer on the Bones, vol. ii.

Compound Luxations.—We shall conclude the present article with a few remarks on the treatment of compound dislocations. The luxation of a large joint, being conjoined with an external wound, leading into the capsular ligament, is a circumstance that has a particular tendency to increase the danger of the accident. In many cases we see injuries of this description followed by violent and extensive inflammation, abscesses and sloughing, fever, delirium, and death. When the patient is advanced in years, is much debilitated, or of an unhealthy irritable constitution, compound luxations, especially if attended with much contusion and other injury of the soft parts, and wrongly treated, very often have a fatal termination. This, however, is not the general event of these cases, and whatever may have happened in former times, we now know, that in the present improved state of surgery such accidents mostly admit of cure. We would not, however, by any means insinuate censure against every instance of amputation performed in these cases: we know that such operation is occasionally indispensable immediately when the accident is seen, and we are equally aware, that it may become necessary in a future stage, when extensive abscesses or sloughing, joined with threatening constitutional symptoms, have occurred. Our only design is to recommend the endeavour to cure the generality of compound luxations. But if a case were to present itself, attended with very great contusion and laceration of the soft parts, we should be as earnest advocates for amputation as any practitioners.

The treatment of a compound dislocation requires the reduction to be effected without delay, and with as little violence and disturbance as possible. The limb is then to be placed in splints, with the requisite pads, eighteen-tailed bandage, &c. The wound is to be freed from any dirt or extraneous matter, and its lips accurately brought into contact with strips of adhesive plaster. The joint is to be covered with linen wet with the saturnine lotion, the bandage is to be loosely laid down, and the splints fastened on with their proper straps or pieces of tape, and the limb is to be kept perfectly at rest in an eligible posture. The patient, if strong and young, is to be bled. This last practice may be more freely adopted in the country than in London, or large

hospitals. Purgings, however, must never be omitted, and an anodyne, the first night or two, will be highly proper. Saline draughts, antimonial, and a low regimen, are also indicated during the first few days of the symptomatic fever which commonly follows so serious an accident.

If the case takes a favourable course, the constitutional disposition will not be excessive, nor will the pain and inflammation of the limb be immoderate. Sometimes the wound even unites, more or less, without suppuration, a circumstance of the highest importance, as tending more than any thing to lessen the danger, by changing the case, as it were, from a compound into a simple one. In other cases, the wound is not united, but the inflammation and suppuration are not violent or extensive, and there is every reason to expect ultimate success. When the wound is disposed to unite favourably, lint and adhesive plaster are the best dressings. In other instances, while the suppuration is at all copious, or the inflammation high or extensive, emollient poultices are most eligible.

When the symptomatic fever and first inflammatory symptoms are over, and there is much discharge, attended with marks of approaching weakness, the patient is to be allowed more food, and be directed to take bark, cordials, porter, wine, &c. If his nights are restless, he must have opiates; and, in short, all such medicines as his particular complaints may require, are to be prescribed.

When the inflammation of a compound dislocation is violent or extensive, general bleeding, and the use of leeches, are the most effectual means of counteracting the mischief.

In certain cases, the most skilful treatment is unavailing. The joint and limb become affected with considerable pain and swelling; the fever runs high; delirium comes on; and the patient may even perish from the violence of the first symptoms, the limb being generally at the same time attacked with gangrene. If these first dangers are avoided, the wound may not heal favourably; the inflammation may be extensive; large abscesses under the fasciæ may be formed; and the hectic symptoms and sinking state of the patient may make the only chance of recovery depend upon amputation. But even this operation is sometimes deferred till too late, and the patient must be left to his miserable fate.

Whoever gives the smallest reflection to the nature of compound fractures, will perceive, that it is often a matter of the last importance to make a right decision at the very beginning, whether amputation should be immediately done, or whether an attempt to save the limb ought to be made. In some instances, the patient's sole chance depends upon the operation being performed at once without the least delay, and the opportunity of doing it never returns.

Thus, when great inflammation and a rapid mortification of the limb follow the accident, the patient may die before the sloughing has shown the least inclination to stop.

But, besides this first critical period, the surgeon often has to exercise a nice degree of judgment in a future stage of the case; we mean when the suppuration is copious, and the health much impaired. Here the practitioner may err in taking off a limb that might be saved; or he may commit a worse fault, and make the patient lose his life in a fruitless attempt to save the member. No precepts can form the right practitioner in this delicate part of surgery; genius alone cannot do it; we would add, mere experience, however great, cannot do it: the opportunity of making observations, and the talent of pronouncing by them, are here the things which make the consummate surgeon.

LUXEMBOURG, FRANCIS-HENRY DEMONTMORENCY, Duke of, in *Eng. cyc. ly.*, a celebrated French general, son of the

count of Bouteville, who was beleaded under Lewis XIII. for fighting a duel, was born in 1628. He was educated for the military profession, and at the age of fifteen was, at the battle of Rocroi, under the illustrious Condé, whose various fortunes he followed. He resembled that hero in several of his qualities, and was himself admitted a duke and peer of France. In 1667, he was promoted to a lieutenant-generalship, and in that character he was, in the following year, active in the conquest of Franche-Comté. He had the chief command, in 1672, in the invasion of Holland, where, in one campaign, he took a number of towns, and gained the battles of Bodegrave and Woerden: after this, he made a famous retreat with an army of 20,000 men, against 70,000. In 1675, he was opposed to the prince of Orange, and by his success obtained the dignity of marshal of France. In 1690, he gained the battle of Fleurus, which was followed by several other very important victories. Previously to these last-named successes he had been detained a prisoner in the Bastille more than a year, on charges connected with his amours, to which, notwithstanding the deformity of his person and features, he was much addicted. He died in 1695, and with him, it has been said, terminated the victories and grandeur of Lewis XIV. No general after him possessed, to so high a degree, the attachment and confidence of the soldiers. His uniform success, when contending with king William, rendered him an object of jealousy to that prince, who once, in the bitterness of his heart, called him a "hump-back;" "What does he know of my back," said the marshal, "he never saw it?" Moreri.

LUXEMBURG, in *Geography*, one of the ten Catholic provinces of the Netherlands before the French revolution, bounded on the north by the bishopric of Liege, and duchies of Limburgh and Juliers, on the E. by the electorate of Treves, and on the S. and W. by France; to which, by a late treaty, it is now annexed, constituting, in part, the department of the *Forêts*; which see. It lies in the centre of the forest of Ardennes. Its soil, though not fertile, produces some corn; but it furnishes a good breed of cattle, wine, all sorts of game, iron-works, and founderies for cannon, which are the chief source of its wealth. It is watered by many small rivers which run into the Meuse and Moselle. It contains, besides the city of Luxemburg, 23 other smaller towns.

LUXEMBURG, a city of France, principal place of a district, and capital of the department of the *Forêts*. From being a castle, built by the people of Treves, it was enlarged by the Romans, and called "Augusta Romanorum." When Merovingus, king of France, conquered the country, it was called the "city of the sun," because the sun was anciently adored there, as the moon was at Arlon, Jupiter at Ivoy, now called Carignan, and Mars at Marche en Famine. This city is small, but strong, on account both of its situation and fortifications, which were thought to be the strongest in Europe. It is divided by the river Alzitz, which runs through it, into the Upper and Lower Towns; the former being situated on a rock, the latter in a plain. Its number of inhabitants is estimated at about 10,000, its two cantons contain 20,522, on a territory of 247½ kilometres, in 14 communes. Having frequently changed masters, being at one time in the possession of France, at another time in that of Spain, again under the dominion of the States General, to which it was ceded by the barrier treaty in 1701, and afterwards, viz. in 1715, possessed by the emperor; it was blockaded by the French, after they had acquired by arms the surrounding country, and surrendered to them on the 7th of June, 1795, by capitulation. The surrender of Luxemburg put the French in possession of the whole country on the left of the Rhine,

except Mentz; 50 miles S.S.E. of Liege. N. lat. 49° 40'. E. long. 6° 13'.

LUXEUIL, a town of France, in the department of the Upper Saône, and chief place of a canton, in the district of Lire; 14 miles N.E. of Vesoul. The place contains 3080, and the canton 13,261 inhabitants, on a territory of 190 kilometres, in 27 communes. N. lat. 47° 49'. E. long. 6° 27'.

LUXOR, **LUXOREIN**, or *Akfor*, a village of Egypt, on the right side of the Nile, the site of which is the ruins of the celebrated city of *Thebes*, which see. Of these ruins we shall now only mention from Mr. Browne's Travels (p. 135.), that they extend for about three leagues in length along the Nile. East and west they reach to the mountains, a breadth of about 2½ leagues. The river is here about 300 yards broad. The circumference of the ancient city mull, therefore, have been about 27 miles. This ingenious traveller is of opinion that Luxor and Akfor are corruptions of El Kufur, the real term, which is still applied to the ruins by the Arabs; 18 miles S. of Kous.

LUXURIANT PLANTS, a term in *Gardening*, signifying such as become greatly augmented in growth beyond their common natural state, and which rarely acquire that degree of perfection which is the case with those of more moderate growths. This sometimes happens from the excess of nourishment, and sometimes from the nature of the plants.

But it is produced differently; sometimes prevailing in the whole plant, sometimes in particular parts, as in some of the shoots, and frequently in the flowers.

The first of these may be considered such as shoot much stronger than plants of the same species generally do, and it happens both in herbaceous plants and trees, &c. which never attain perfection so soon as the more moderate growers: thus, many sorts of esculent plants, which shoot luxuriantly to leaves and stalks, &c. as cucumbers, melons, cabbages, cauliflowers, turnips, radishes, beans, peas, &c. never arrive so soon to perfection as those of moderate growth; and such plants as appear to be naturally of themselves of a very luxuriant nature, are very improper to stand, from which to save seed for future increase.

And this is also the case in fruit-trees; as such as are very luxuriant shooters are much longer before they attain a bearing state than those of middling growth, and they never bear so plentifully, or have the fruit attain such perfection. This luxuriance is frequently acquired by unskilful pruning, especially in wall-trees, &c. as it is often the practice, when wall or espalier trees assume such a growth, to cut all the shoots short; by which, instead of reducing the tree to a moderate state of shooting, it has its vigour increased, as too considerable shortening of strong shoots promotes their throwing out still stronger, and producing more abundant or superfluous wood. Therefore, in pruning very luxuriant espalier and wall-fruit trees, they should be assisted somewhat in their own way, as it were, by training in plenty of shoots annually for a year or two, to divide the redundancy of sap; or, in the summer and winter prunings, always leaving them rather thicker than in the common practice, and mostly at full length, unless it be necessary to shorten such as are of very considerable length, or in some particular part of the tree, to force out a supply of wood to fill a vacancy. Some sorts of fruit-trees should, indeed, never be generally shortened in the common course of pruning, except in casual, very extended, irregular growths, or occasionally for procuring a supply of wood, as mentioned above. This is particularly necessary in apples, pears, plums, cherries, and fig-trees; for, if generally shortening was to be practised in

in these sorts, they would continue shooting every year so luxuriantly to wood, that they would never form themselves into a proper bearing state: even in those trees where shortening is necessarily practised in winter, in most of the annual supplies of shoots, as in peaches, nectarines, &c. in cases of luxuriant growth, it should be very sparingly performed, the general shoots not being cut very short, and some of the most vigorous left almost or quite at the full length. This is the proper method to reduce luxuriant trees to a moderate growth, and to a bearing state; as by training the shoots thicker, and leaving them longer, and continuing it for a year or two, the redundant sap, having greater scope to divide itself, cannot break out with that luxuriance as when it has not half the quantity of wood to supply with nourishment, as in the case of short pruning. See ESPALIER, WALL-TREES, and PRUNING.

This state seldom occurs with any continuance in standard-trees, where permitted to take their natural growth, except in casual straggling shoots, which should always be taken out. Over-luxuriant shoots are mostly met with in trees and shrubs; but require more particularly to be attended to in the culture of the fruit-tree kind, especially those of the wall and espalier sort, which undergo annual pruning.

They are such as shoot so vigorously in length and substance, as greatly to exceed the general growth of those usually produced on the same kind of plant or tree, and are sometimes general, but in other cases only happen to particular shoots in different parts of a tree, &c. They are discoverable by their extraordinary length and thickness, and by their vigour of growth, which always greatly impoverishes the other more moderate shoots in their neighbourhood, and likewise the fruit, &c. as well as often occasions a very irregular growth in the respective trees. Such shoots frequently occur in wall and espalier fruit-trees, and are the effects of injudicious pruning. When they are in general wholly so, they should be managed as directed above; but when only in particular shoots here and there in a fruit tree, or other tree or shrub under training, such shoots being of such a very luxuriant nature as to draw away the nourishment, at the expence of the adjacent moderate shoots, and which, by their vigorous irregular growth, cannot be trained with any degree of regularity; they should for the most part, as soon as discoverable, in the summer or winter prunings, be cut out, taking them off as close as possible to the part of the branch whence they originate, that no eye may be left to shoot again; unless such a shoot should rise in any part of a tree or shrub, where a further supply of wood may be requisite; in which case it may be retained and shortened as convenient, to force out a supply of more shoots laterally to fill the vacancy.

Where it prevails in other trees and shrubs than those of the fruit kind, they should have occasional attention, pruning them in regular order in their younger advancing growth, or afterwards occasionally in particular sorts, as may be necessary: observing, in either, when any straggling shoots, &c. assume a very luxuriant rambling growth, greatly exceeding the other general branches, that they may be more or less reduced or cut entirely away close to their origin, as may be most expedient, according to the nature of growth of the trees or shrubs, either in summer or winter, &c.

Most double flowers may be considered as luxuriant, especially such as have the cup or corolla multiplied, or so augmented in the number of their leaves or flower-petals inward, as to exclude some part of the fructification, as the same thing occurs in flowers as in esculent plants and fruit-trees, from their over-luxuriant growth; for, as the flower is designed for perfecting the fruit and seed, when the petals are

multiplied to the diminution of the stamina, &c. no impregnation ensues, and of course no fruit or seed is produced.

In the double varieties of most kinds of flowers produced on ornamental flowering plants, this luxuriance is generally considered as a superior degree of perfection; and has different modifications.

The highest degree of this sort of luxuriance is met with in carnations, anemones, ranunculuses, the poppy, lychnis, peony, narcissus, violet, and some others.

LUXURY, says Mr. Hume, (Ess. vol. i. p. 285.) is a word of an uncertain signification, and may be taken in a good as well as a bad sense. In general, it means great refinement in the gratification of the senses; and any degree of it may be innocent or blameable, according to the age, or country, or condition of the person. The bounds between the virtue and the vice cannot here be exactly fixed, more than in other moral subjects. To imagine, that the gratifying of any sense, or the indulging of any delicacy in meat, drink, or apparel, is of itself a vice, can never enter into a head, that is not disordered by the frenzies of enthusiasm. "I have, indeed," says our author, "heard of a monk abroad, who, because the windows of his cell opened upon a noble prospect, made a covenant with his eyes never to turn that way, or receive so sensual a gratification." Such is the crime of drinking Champagne or Burgundy, preferably to small beer or porter. These indulgences are only vices, when they are pursued at the expence of some virtue, as liberality or charity; in like manner as they are follies, when for them a man ruins his fortune, and reduces himself to want and beggary. When they entrench upon no virtue, but leave ample subject whence to provide for friends, family, and every proper object of generosity or compassion, they are entirely innocent, and have in every age been acknowledged such by almost all moralists. To be entirely occupied with the luxury of the table, for instance, without any relish for the pleasures of ambition, study, or conversation, is a mark of stupidity, and is incompatible with any vigour of temper or genius. To confine one's expence entirely to such a gratification, without regard to friends or family, is an indication of a heart destitute of humanity or benevolence. But if a man reserve time sufficient for all laudable pursuits, and money sufficient for all generous purposes, he is free from every shadow of blame or reproach. Since luxury may be considered either as innocent or blameable, one may be surpris'd, says Mr. Hume, at those preposterous opinions which have been entertained concerning it; while men of libertine principles bestow praises even on vicious luxury, and represent it as highly advantageous to society; and on the other hand, men of pure morals blame even the most innocent luxury, and represent it as the source of all the corruption, disorders, and factions incident to civil government. This author endeavours to correct both these extremes, by proving, 1st, that the ages of refinement are both the happiest and the most virtuous; and 2dly, that wherever luxury ceases to be innocent, it also ceases to be beneficial; and when carried a degree too far, is a quality pernicious, though perhaps not the most pernicious to political society. In proof of the first point, he considers the effects of refinement both on private and public life. For his reasoning we must refer to the Essay, above cited. Industry, knowledge, and humanity, says our author, are linked together by an indissoluble chain, and are found, from experience as well as reason, to be peculiar to the more polished, and, what are commonly denominated, the more luxurious ages. He adds, that these advantages are not attended with any disadvantages that bear any proportion to them. The more men refine upon pleasure, the

less will they indulge in excesses of any kind; because nothing is more destructive to true pleasure than such excesses. Besides, industry, knowledge, and humanity diffuse their beneficial influence beyond the sphere of *private* life, on the *public*, and render the government as great and flourishing as they make individuals prosperous and happy. Our author concludes his Essay on "Refinement in the Arts," with the following observations. "Luxury, when excessive, is the source of many ills; but is in general preferable to sloth and idleness, which would commonly succeed in its place, and are more hurtful both to private persons and to the public. When sloth reigns, a mean uncultivated way of life prevails amongst individuals, without society, without enjoyment. And if the sovereign, in such a situation, demands the service of his subjects, the labour of the state suffices only to furnish the necessities of life to the labourers, and can afford nothing to those who are employed in the public service."

An excellent writer, to whom we shall next refer, takes occasion, from a consideration of the mode of living which actually obtains in any country, to illustrate the true evil and proper danger of luxury. Luxury, as it supplies employment and promotes industry, allures population. But it is attended with a consequence, which counteracts and often overbalances these advantages. When, by introducing more superfluities into general reception, luxury has rendered the usual accommodations of life more expensive, artificial, and elaborate; the difficulty of maintaining a family, conformably with the established mode of living, becomes greater, and what each man has to spare from his personal consumption proportionably less: the effect of which is, that marriages become less frequent, agreeably to the maxim, which lies at the foundation of this reasoning, that men will not marry to *sink* their place or condition in society, or to forego those indulgences, which their own habits, or what they observe amongst their equal, have rendered necessary to their satisfaction. This principle is applicable to every article of diet and dress, to houses, furniture, and attendance; and this effect will be felt in every class of the community. For instance, the custom of wearing broad cloth and fine linen repays the shepherd and flax-grower, feeds the manufacturer, enriches the merchant, gives not only support but existence to multitudes of families: hitherto, therefore, the effects are beneficial; and were these the only effect, such elegancies, or, if they may be so called, such *l'etiquette*, could not be too general. But here follows the mischief: when once fashion hath annexed the use of these articles of dress to any certain class, to the middling ranks, for example, of the community, each individual of that rank finds them to be *necessaries* of life: that is, finds himself obliged to comply with the example of his equals, and to maintain that appearance which the custom of society requires. This obligation creates such a demand upon his income, and withal adds so much to the cost and burthen of a family, as to put it out of his power to marry, with the prospect of continuing his habits or of maintaining his place and situation in the world. We see, in this description, says our author, the cause which induces men to waste their lives in a barren celibacy; and this cause, which impairs the very source of population, is justly placed to the account of luxury. It appears, upon the whole, to be the tendency of luxury to diminish marriages, and that in this tendency the evil of it resides. Hence it may be inferred, that of different kinds of luxury, those are the most innocent which afford employment to the greatest number of artists and manufacturers; as those, in other words, in which the price of the work bears the greatest proportion to that

of the raw material. Thus, luxury in dress, in furniture, is universally preferable to luxury in eating, because the articles which constitute the one, are more the production of human art and industry, than those which supply the other. We may also conclude, that it is the *difference*, rather than the *degree*, of luxury, which is to be dreaded as a national evil. The mischief of luxury consists in the obliquation that it forms to marriage. But, as it is only a small part of the people in any country that is composed by those of higher rank, the facility, or the difficulty, of supporting the expence of their station, and the consequent increase or diminution of marriages among them, will have but little influence on the state of population. As long as the prevalence of luxury is confined to a few of elevated rank, much of the benefit is felt, and little of the inconvenience. But when the imitation of the same manners descends, as it always will do, into the mass of the people; when it advances the requisites of living beyond what it adds to men's abilities to purchase them, then it is that luxury checks the formation of families, in a degree that ought to alarm the public. To all which we may add, that the condition most favourable to population is that of a laborious, frugal people, ministering to the demands of an opulent, luxurious nation; because this situation, while it leaves them every advantage of luxury, exempts them from the evils which naturally accompany its admission into any country. Paley's *Princ. of Mor. and Pol. Philos.* vol. ii.

In our country there was formerly a multitude of penal laws intended for restraining excess in apparel; chiefly made in the reigns of Edward III., Edward IV., and Henry VIII., against piked shoes, short doublets, and long coats, all of which were repealed by statute 1 Jac. I. c. 25. Excess of diet, which is one species of luxury, is still prohibited by 1 Edward III. stat. 3, which ordains that no man shall be served at dinner or supper with more than two courses: except upon some great holidays there specified, in which he may be served with three. See *SUMPTUARY LAWS*.

LUYTS, JOHN, in *Biography*, a philosopher and astronomer, was born in North Holland in 1665. He became professor of philosophy and mathematics at Utrecht, where he died in 1721. He wrote 1. An Astronomical Work, in which he rejected the Copernican system, entitled "Instituta astronomica in qua doctrina sphaerica, atque theoria, intermixto usu sphaerae celestis, et variis chronologicis, pertractantur." 2. An Introduction to Modern and Ancient Geography, with many plates. In all that he wrote and taught he showed himself a great partisan of the Aristotelian philosophy, in opposition to that of Descartes, Moveri.

LUZ, LA, in *Geography*, a sea-port town of the island of Canary; five miles N. of Ciudad de las Palmas.—Also, a town of France, in the department of the Higher Pyrenees, and chief place of a canton, in the district of Argeles. The place contains 2135, and the canton 6222 inhabitants, on a territory of 552 kilometres, in 17 communes.

LUZARA, a town of Italy, in the department of Minicio; 16 miles S. of Mantua.

LUZARCHES, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Pontoise; 5 leagues N. of Paris. The place contains 1696, and the canton 11,411 inhabitants, on a territory of 180 kilometres, in 22 communes. N. lat. 49° 5'. E. long. 2° 30'.

LUZECH, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 2½ leagues from Cahors. The place contains 2049, and the canton

canton 10,504 inhabitants, on a territory of 162½ kilometres, in 12 communes. N. lat. 44° 26'. E. long. 1° 23'.

LUZERATH, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Coblenz. The place contains 614, and the canton 2525 inhabitants, in 12 communes.

LUZERNE, a large county of Pennsylvania, bounded north by Tioga county in New York, east and south-east by Northampton, west by Lycoming and Northumberland counties; about 79 miles in length from north to south, and 75 in breadth from east to west, divided into 19 townships, and containing 2 churches, 33 saw-mills, 24 grist-mills, 2 fulling-mills, and 1 oil-mill. The number of inhabitants is 128,399. Near the Susquehanna river, which, with its tributary streams, well waters it, the soil is very fertile, and produces good crops of wheat, flax, and hemp. The northern parts abound with pine, timber, and sugar-maple. In the townships of Wilksbarre, Kingston, Exeter, and Plymouth, are large beds of coal. Coal and bog-iron are found in several places, and two forges have been erected. In this county are many remains of ancient fortifications, which are of an elliptical form, and covered with large white oak-trees. Its chief town is Wilksbarre.

LUZIOLA, in *Botany*, Juss. 33. An annual Peruvian grass, which Dombey took for a *Zizania*. It is described by Jusseu as monœious, without any calyx; the corolla of two valves, without awns. Male flowers in a loose terminal spike. Stamens usually eight, sometimes nine or ten; anthers stalked. Female flowers panicle, inferior, much smaller. Styles two. Seed ovate, naked.

LUZULA, a genus established by Decandolle in his edition of Lamarck's *Flora Française*, v. 3. 158; and adopted by Mr. R. Brown, Prodr. Nov. Holl. v. 1. 591. It consists of such Linnæan *Junci* as have a capsule of a single cell, with only three seeds, as is the case with *J. campylois*, Linn. (Juncoides; Mich. Gen. 41. t. 31.) Whether the small number of the seeds be a sufficient character, seems to us at best doubtful, considering how various their number is in other *Junci*. The capsule having one cell or three is certainly of no importance, in either the three-seeded or many-seeded species; some having perfect partitions from the centre of their valves, others more or less of a ridge there in the place of them. The capsule of *Juncus Forsk.*, Engl. Bot. t. 1293, for instance, which by the number of its seeds should be a *Luzula*, has a capsule of three cells. It is indeed much to be wished, that plants so unlike the habit of most *Junci* could, by any sound character, be separated from them; but without such they are best as they are.

LUZURIAGA, so called by the authors of the Flora Peruviana, in honour of a Spanish botanist, or patron of the science, of the same name. Ruiz et Pavon Fl. Peruv. Brown Prodr. Nov. Holl. v. 1. 281.—Class and order, *Hamambia Monogypia*. Nat. Ord. *Sarmentaceæ*, Linn. *Ajphoditi*, Juss. *Alphodææ*, Brown.

Eff. Ch. Calyx none. Corolla in six deep, equal, spreading, beardless segments, deciduous. Filaments inserted into the base of each segment, thread-shaped, smooth, curved at the point; anthers arrow-shaped, cohering, longer than the filaments. Style thread-shaped, with three furrows; stigma simple. Berry with a few, nearly globose, seeds.

This genus consists of climbing weak shrubs, with simple ribbed leaves. Flowers cymose or umbellate, terminal and axillary; their footstalks as it were articulated with the rather tapering base of the flower. Berry black, sometimes enclosing only a single seed. Mr. Brown is not quite cer-

tain of his genus being precisely the same with that of the Flora Peruviana. He defines two New Holland species.

1. *L. cymosa*. Cymes terminal, deeply divided. Branches round. Young branches striated, smooth. Found near Port Jackson, as well as within the tropic.

2. *L. montana*. Umbels axillary, stalked. Branches striated, rough. Found near Port Jackson.

LUZY, in *Geography*, a town of France, in the department of the Nièvre, and chief place of a canton, in the district of Châteaun-Cléon; 5 leagues S.S.E. of Moulins-en-Gilbert. The place contains 1607, and the canton 8743 inhabitants, on a territory of 417½ kilometres, in 9 communes.

LUZZANA, a town of Italy; 22 miles S. of Mantua.

LUZZI, a town of Naples, in Calabria Citra; 4 miles S. of Bitugiano.

LUZZO MARINO, in *Ichthyology*, a name given by the Italians to the fish called by the ancient Greek writers, and many of the modern Latin authors, *fisherius*; and by Pliny, Varro, and some other of the old Roman authors, *judis*. Gaza has called it the *colleolus*, and the French, at this time, call it *spet*. Salvian has given the figure of it, but it is an imperfect one; for he has omitted the first fin of the back.

LYBIA, in *Ancient Geography*. See **LIBYA**.

LYCÆA, *Arctos*, in *Antiquity*, an Achaian festival resembling the Roman *lupercalia*, in which the conqueror was rewarded with a suit of brazen armour.

LYCANTHROPIA, in *Ancient Medicine*, from *lycos*, a wolf, and *anthropos*, man, as it were *man to be*; a term applied to that variety of mania or melancholy, which induced the persons affected to wander out in the night, howling and making other noises, frequenting church-yards, or places of burial; in which circumstances they were supposed to imitate or to resemble wolves. Aetius and Paul of Aegina have described such patients as pale, with dry and hollow eyes, parched tongue and mouth, excessive thirst, and perpetual sores on their legs, in consequence of the frequent accidents which they met with. The same term was also applied to those maniacs, who fancied themselves transformed into wolves. The appellation of *lycanthropia* was also given to the disease, when the patients imitated the manners of dogs, or imagined themselves to be changed into these animals.

LYCAON, in *Zoology*. See **Black Fox**.

LYCAONIA, in *Ancient Geography*, a province of Asia Minor, south of Galatia. According to Strabo, Hauria made a part of it. It was situated between mountains, and is supposed to have derived its name from *lycos*, a wolf, because the country, from its situation, formed a proper retreat for those animals. The principal places of Lycaonia, according to Ptolemy, were Adapfus, Cana, Iconum, Paralais Coena, Castis, and Baratta. The apostles of this country are said to have been St. Paul and St. Barnabas. The notitia of Hierocles reckons in this province 15 episcopal towns.

LYCEUM, *Arctos*, in *Antiquity*, the name of a celebrated school, or academy at Athens, where Aristotle explained his philosophy.

The place was a grove in the suburbs of Athens, which had previously been used for military exercises. It was composed of porticoes, and trees planted in the quincunx form, where the philosophers disputed walking. Hence *philosophy of the Lyceum* is used to signify the philosophy of Aristotle, or the Peripatetic philosophy. Simas observes, that the Lyceum took its name from its having been originally a temple of Apollo Lyceus; or rather, a portico or gallery built by Lyceus, son of Apollo; but others mention it to have

have been built by Pisistratus, or Pericles. Here he delivered his lectures to a promiscuous auditory in the evening, when the Lyceum was open to all young men without distinction; but in the morning his disciples were more select, and such as had been previously instructed in the elements of learning, and discovered abilities and dispositions suited to the study of philosophy. The latter he called his morning walk, and the former his evening walk. Aristotle continued his school in the Lyceum twelve years.

LYCHNANTHUS, in *Botany*, a name given by Gmelin to the *Cucubalus baccifer* of Linnaeus, which is superfluous, this plant being perhaps the only true *Cucubalus*; see that article.

LYCHNIDEA. See **PHLOX** and **SELAGO**.

LYCHNIS, λυχνίς of the Greeks, which word also signifies a lamp. Hence some have supposed that its botanical application arose from the down of the plant having been used to make wicks for lamps. This, however, by no means appears to have been the fact. The most probable and apparent explanation of the name is from the resemblance of the calyx to a lantern, its sides being semi-transparent between the ribs or veins, or the whole, in some instances, quite membranous, round, and inflated, like the horn lanterns still used by the Chinese. Possibly the appearance of the stigmas, flaments, or crown of the corolla, in several species, might favour the idea of a lamp with its flame. We must recollect that this name of *Lychnis* has been always used, with great latitude, for all the Campion tribe, by the old botanists; though now restricted, by Linnaeus and his followers, to one particular genus of that family. The short mention in Dioscorides, of his λυχνίς, is quite insufficient to determine either the wild or garden plant of which he speaks. Linn. Gen. 231. Schreb. 312. Willd. Sp. Pl. v. 2. 807. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 493. Ait. Hort. Kew. ed. 2. v. 3. 132. Juss. 302. Lamarck Illustr. t. 391. Gært. t. 130.—Class and order, *Decandria Pentagynia*. Nat. Ord. *Garyophyllet*, Linn. Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, oblong, tubular, membranous, five-toothed, permanent. *Cor.* Petals five; their claws the length of the calyx, flat, each crowned with a double erect seale; border flat, wedge-shaped, often divided. *Stam.* Filaments ten, longer than the calyx, fixed to the claws of the petals, five alternate ones later than the rest; anthers incumbent. *Pist.* Germen superior, nearly ovate; styles five, awl-shaped, longer than the flaments; stigmas downy, reflexed contrary to the motion of the sun. *Peric.* Capsule more or less ovate, clothed with the calyx, of from one to five cells, opening by five rigid reflexed teeth at the top. *Seeds* numerous, roughish, somewhat kidney-shaped.

Obs. *L. dioica* has the flaments and pistils in separate flowers and on different plants. *L. Viscaria* has undivided petals, and a capsule of five cells. Some other species are esteemed to vary in the number of their styles from five to four, or even three. *L. apetala* has the corolla concealed within the calyx.

Ess. Ch. Calyx of one leaf, oblong. Petals five, with claws; the border usually divided. Capsule superior, with five teeth at its orifice, of from one to five cells.

Ten species of *Lychnis* occur in the fourteenth edition of *Syst. Veg.*, of which one, *alpestris* of the *Supplementum*, is made by Jacquin, Aiton, and Willdenow, a *Silene*, surely with great propriety. But there can be no doubt that *quadridentata* ought to be referred to the same genus, as having naturally only three styles, or at most but four. These two species being removed hence, the above-men-

tioned anomaly in the number of the styles in the present genus is done away; for *alpina*, reputed to have four styles, is now known to have naturally, if not invariably, five; see Engl. Bot. t. 2254. We therefore retain but eight of the species of Linnaeus, or rather of Murray, for Linnaeus was originally correct respecting the above. To these eight two are added by Willdenow, from Aiton and Lamarck.

1. *L. chalcidonica*. Scarlet Lychnis. Linn. Sp. Pl. 625. Curt. Mag. t. 257. Ger. em. 466.—Tufts terminal, level-topped, many-flowered. Leaves ovate, rough, somewhat undulated.—This is said by Gmelin to grow wild in all parts of Russia and Siberia. It is one of the oldest ornaments of our flower-gardens, being a hardy perennial, very showy, and remarkable for the rich deep scarlet of its blossoms, especially when double. These appear in June and July, forming a large, dense, convex, terminal tuft, two or three inches wide. The stem is three or four feet high, round, hairy, leafy, but little branched. Leaves sessile, opposite, pointed, wavy, rough, dark green, clasping the stem with their broad, ovate, often combined, bases. We have never seen the pale red, nor the white varieties, mentioned by authors.

2. *L. Flos cuculi*. Meadow Lychnis, or Ragged Robin. Linn. Sp. Pl. 625. Curt. Lond. fasc. 1. t. 33. Engl. Bot. t. 573. (Armoria pratenfis; Ger. em. 600.)—Petals in four deep, linear segments. Leaves lanceolate, smooth. Fruit roundish, of one cell.—Frequent in moist meadows throughout Europe, flowering in June. The root is perennial. Stem twelve or eighteen inches high, with rough angles, viscid above. Leaves narrow. Panicle forked. Petals pink, very delicate, with a brown, angular, smooth calyx. There is a double variety, and some mention a white one.

3. *L. Viscaria*. Red German Catchfly. Linn. Sp. Pl. 625. Fl. Dan. t. 1032. Engl. Bot. t. 788. (Muscipula angustifolia; Ger. em. 601.)—Petals undivided. Leaves linear-lanceolate, smooth. Fruit of five cells.—Native of dry or rocky pastures in the north of Europe. We have gathered it in the fissures of rocks, a mile south of Edinburgh, and have it also from Perthshire. It flowers in May and June. A double variety is common in gardens, and a pure white one is sometimes seen. The roots are woody, tufted, and perennial. Herb smooth. Stem a foot high, angular, brown and very clammy under each joint. Leaves narrow. Flowers in a dense, forked, oblong bunch or spike. Petals crimson, only slightly emarginate, not cut or cloben. Capsule ovate, of five cells, though this species is so nearly allied in habit to the foregoing, whose capsule has but one cell.

4. *L. alpina*. Red Alpine Campion. Linn. Sp. Pl. 626. Tour in Lapland, v. 2. 19. Curt. Mag. t. 394. Fl. Dan. t. 65. Engl. Bot. t. 2254.—Smooth. Petals cloben. Flowers corymbose. Leaves linear-lanceolate.—Native of the Lapland, Siberian, Swiss and Pyrenean mountains; discovered on the Clova mountains of Angusshire, by Mr. G. Don, in 1795. It is much smaller than the last, and not at all viscid. The petals are divided at least half way down, and their crowns but small. See Sm. Tr. of Linn. Soc. v. 10. 342, for the confusion and contrariety of description which has attended this species.

5. *L. magellanica*. Magellanic Campion. Lamarck Dict. v. 3. 641. Willd. n. 7.—Somewhat hairy. Leaves linear. Petals cloben, scarcely longer than the calyx.—Fruit of one cell.—Gathered by Commerçon in the Straits of Magellan. We know this species solely by Lamarck's account. He compares its habit and foliage to that of Thrift, *Statice Armorica*, but observes that it is next akin to *L. alpina*, differing in having narrower, and somewhat downy leaves, fewer and larger

larger flowers, whose petals scarcely exceed the length of their bell-shaped calyx.

6. *L. fibrica*. Siberian Campion. Linn. Sp. Pl. 626. —Hairy. Leaves lanceolate. Stem forked, many-flowered. Petals cloven, twice as long as the calyx. Fruit of one cell. —Gathered in Siberia by Gmelin, who sent it to Linnaeus, but it does not find a place in the *Flora Sibirica*. This has greatly the habit of *Silene alpestris* above-mentioned, but is all over hairy; the petals more obtuse, and less deeply cloven; the styles five. The root is very long and simple, tufted at the crown, bearing numerous stems a span high, which are about twice forked. Calyx bell-shaped, tapering at the base. Petals apparently reddish. Capsule ovate, of one cell, with recurved irregular teeth.

7. *L. leia*. Small Portugal Campion. Ait. Hort. Kew. ed. 1. v. 2. 118. —Petals cloven. Flowers solitary. Leaves linear-lanceolate, smooth. Calyx with ten ribs. —Brought from Portugal, by the late Dr. Edward Whittaker Gray, in 1778, to Kew garden, where it is said to be a hardy annual, flowering in July. If this species still exists, it ought to be figured in some periodical work; it being greatly to be wished that the authors of such would prefer unpublished plants to those already often delineated. We know of no plate of this or the last-mentioned.

8. *L. coronata*. Chinese Lychnis. Thunb. Jap. 187. Linn. Syst. Veg. ed. 14. 435. Curt. Mag. t. 223. (*L. grandiflora*; Jacq. Col. v. 1. 149. Ic. Rar. t. 84. *Hedonia sinensis*; Lour. Cochinch. 286; see *HEDONIA*). —Leaves elliptic-lanceolate, smooth. Flowers axillary or terminal, solitary. Petals jagged. —Native of China and Japan, from whence Dr. Fothergill procured the plant in 1774. It flowers in June or July, or later, and must be kept in the greenhouse in winter, or at least protected by extraordinary covering, if left in the border. The root is perennial. Stem weak, round, smooth, two feet high. Leaves elliptic-lanceolate, pointed, smooth, pale beneath. Flowers remarkable for their great size, sharply jagged petals, and red-lead, very vivid, colour.

9. *L. diaica*. Red or White Field Campion. Linn. Sp. Pl. 626. —a. (red) Curt. Lond. fasc. 2. t. 32. Engl. Bot. t. 1579. —b. (white) Fl. Dan. t. 792. Engl. Bot. t. 1580. Leaves hairy. Flowers dioecious. Fruit of one cell. Crown of each petal four-cleft. —A very common plant throughout Europe; the red-flowered kind in hedges and shady bushy places in spring; the white more usually in fields or open situations in summer. The latter is a stronger plant, and from its evening fragrance has been called *L. vespertina* by Dr. Sibthorp, while the former is his *diurna*; see Fl. Ox. m. 145, 146. Both are usually dioecious, but not invariably so. There is a bluish-coloured variety, otherwise moist like the white; but we have found it in cultivation soon evanescent. The roots of both are perennial. Plant hairy and somewhat viscid, two or three feet high. Stem forked. Leaves ovate or lanceolate. Limb of each petal cloven half way down, generally with two small acute lateral lobes, its crown moreover consisting of two obtuse central teeth, and two acute lateral ones.

10. *L. apetalus*. Apetalous Mountain Campion. Linn. Sp. Pl. 626. Fl. Lapp. ed. 2. 150 t. 12. f. 1. —Calyx inflated, longer than the petals. Stem nearly single-flowered. —Native of the mountains of Lapland and Siberia. The root is perennial. Stem, in the Lapland specimens, a span high, and quite simple, single-flowered; in some of Gmelin's, from Siberia, taller, with from three to five flowers. The whole herb is slightly downy. Leaves lanceolate, rather narrow. Flower drooping. Calyx ovate, closed, with ten rough, purplish-brown ribs. Petals small and nar-

row, with an obsolete brownish border, entirely included, along with the stamens and pistil, in the hollow of the calyx. Capsule obtuse, of one cell.

LYCHNIS, in Gardening, contains plants of the hardy, herbaceous, flowery, perennial kind, of which the species cultivated are the scarlet lychnis (*L. chalcidonica*); the red-flowered lychnis, meadow pink, or ragged robin, (*L. flos cuculi*); the Chinese lychnis, (*L. coronata*); the viscous lychnis, or catchfly, (*L. viscaria*); the rose-flowered lychnis, wild red campion, or red bachelor's buttons (*L. diurna*); and the white-flowered lychnis, wild white campion, or white bachelor's buttons, (*L. vespertina*.)

In the first sort there is a variety with very double flowers, of a beautiful scarlet colour, they are produced in close clusters, sitting upon the top of the stalk; when the roots are strong, the clusters of flowers are very large, and make a fine appearance, coming out the latter end of June, and in moderate seasons continue nearly a month in beauty.

Of the fifth sort there is a variety with double flowers, cultivated in gardens by the name of red bachelor's buttons, which is an ornamental plant, and continues long in flower.

And the sixth sort has varieties with purple, or bluish-coloured flowers; with quadrid petals; with hermaphrodite flowers; with double flowers, cultivated in gardens by the name of double white bachelor's buttons.

Method of Culture.—They may be increased with facility in the single sorts by seed, and parting the roots; and in the double ones by dividing or slipping the roots; and sometimes by cuttings of their stalks.

The seed should be sown in the early spring, as in March, in a bed or border of light earth, in an eastern aspect, each sort separate, raking them in lightly, or they may be sown in small drills. The plants come up in two or three weeks, when they should have occasional waterings and hand-weedings; and when the plants are two or three inches high, be planted out in beds or borders, in rows six inches asunder, watering them till fresh-rooted, letting them remain till the autumn or following spring, when they should be transplanted where they are to remain.

Both the single and double may be increased by slipping the roots, but it is more particularly applicable to the double sort, as they cannot with certainty be obtained from seed: the season for performing this work is the autumn after the stalks decay, when the whole root may either be taken up and divided into as many slips as are furnished with proper root-fibres, or the main root stand, and as many of the outer offsets as seem convenient to be slipped off: these slips, when strong, should be planted at once where they are to remain; but when rather small and weak, it is better to plant them in nursery rows, half a foot asunder, to remain a year, and then transplant them for good where they are to stand.

The planting of cuttings of the stalks is mostly practised for the double scarlet sort, when it increases but sparingly by offsets of the root. It is performed in summer, when the stalks are well advanced in growth, but before they flower, or have become hard and woody. Some of them should be cut off close to the bottom, and divided into lengths of four or five joints, planting them in an eastern border of rich, moist loamy earth, two thirds of their length into the ground, leaving only one joint or eye out, watering them directly, and repeating it occasionally with necessary shade in hot weather. They will be well rooted, and form proper plants for transplanting in the autumn. If the cuttings, as soon as planted, are covered down close with hand-glasses, it will greatly promote

mote their rooting, so as to form stronger plants before the winter season comes on.

The only culture they require afterwards is clearing them from weeds in summer, and supporting with stakes those which need it, cutting down and clearing away the decayed stalks in the autumn.

Of the third sort, as being rather more tender, some plants should be planted in pots, for moving under the protection of a frame or greenhouse in the winter season.

All these plants are very ornamental for the pleasure-ground, particularly the double-s. and prosper in any common soil, remaining in all weathers unhurt, being of many years duration in root; and, when of some standing, send up many stalks every spring, terminated by numerous flowers, making a fine appearance in summer. The scarlet double lychnis claims the preference, though the single scarlet sort is also very showy. And all the other species in their respective double-flowered states are ornamental. They are all kept in the nurseries for sale. In planting out, the tallest growers should be placed the most backward, and the others more towards the front.

LYCHNITIS MARMOR. See MARBLE.

LYCIA, in *Ancient Geography*, a country of Asia Minor, originally called Mylias, from the Myliæ, a people of Crete, who settled there, and afterwards Lycia, from Lycus, the son of Pandion, king of Athens; situated upon the Mediterranean, and forming a kind of peninsula, on the west of which was the Glaucus Sinus, and on the east another gulf, in the lower part of which was Attalea. To the south was the Mediterranean. The adjacent countries were on the west, Caria, to the north a small part of Phrygia Pacatiana, and to the north-east Pamphylia. Its boundaries were various at different times. Ptolemy places in Lycia the countries called Mylias and Carbalia, or Cabalia. Pliny says that the Lycians had thirty-six towns; Strabo ascribes to them twenty-three, of which six were very considerable. Lycia was intersected by several chains of mountains, passing from the north and north-east, and extending towards the sea. The most considerable rivers were the Xanthus and Limyrus. Its principal towns were Telmissus, Pinara, Xanthus, Patara, Myra, Limyra, Olympus, and Phaselis. The six towns, particularly noticed by Strabo, after Artemidorus, were Xanthus, Patara, Pinara, Olympus, Myra, and Tlos. The chief mountains of Lycia were Taurus and Chimæra. In the first ages of Christianity, Hierocles reckons as episcopal thirty towns, and Leonie Sage thirty-eight. The inhabitants of Lycia were originally from the island of Crete: and they were for a long time addicted to piracy. Diodorus Siculus, and Plato before him, reckon the Lycians among the Greek nations of Asia, as being descended from the Argians. Although they were governed by kings, it does not appear that the government was completely monarchical; a confederacy having been formed by twenty-three cities, which sent deputies to a general assembly, by which the affairs of the nation were managed. The soil of this country was fruitful, and the air reckoned very wholesome. The Lycians are highly commended by the ancients for their sobriety, and manner of administering justice. They continued to be governed by their own kings after they were subdued by the Persians, paying them tribute. They afterwards fell with the Persians under the power of the Macedonians, and after the death of Alexander, were governed by the Seleucids. When Antiochus the Great was confined by the Romans beyond mount Taurus, Lycia was granted to the Rhodians; but these disobliging the Romans in the war with Perseus, Lycia was declared a free country, and continued in this state till the reign of Claudius, who pro-

voked at their intestine dissensions, reduced their country into the form of a province.

LYCIUM, in *Botany*, *lyceum*, of the Greeks, so called, as is generally supposed, from Lycia, its native country; but what was the precise plant intended, has never been settled by commentators. Dioscorides describes it as a "spinous tree, with twigs three cubits or more in length, bearing thick-set leaves, like box. The fruit is like pepper, black, thick-set, bitter, and smooth. Bark pale. Roots woody." This description accords in many points with some species of the received *Lyceum*, but with none, that we are acquainted with, in every point. Box-thorn. Linn. Gen. 103. Schreb. 136. Willd. Sp. Pl. v. 1. 1057. Mart. Mill. Dict. v. 3. Art. Hort. Kew. ed. 2. v. 2, 3. Sm. Prodr. Fl. Græc. Sibth. v. 1. 155. Juss. 126. Lamarck Illustr. t. 112. Gærtn. t. 132. (Jasminoides; Mich. Gen. 224. t. 105. Duhamel Arb. v. 1. 305.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Luride*, Linn. *Solanæ*, Juss.

Gen. Ch. Cal. Perianth inferior, small, slightly five-lobed, obtuse, erect, permanent. Cor. of one petal, funnel-shaped; tube cylindrical, spreading, incurved; limb small, in five deep, obtuse, spreading segments. Stam. Filaments five, awl-shaped, inserted into the middle of the tube, and closing its orifice with their beard-like hairiness, shorter than the limb; anthers erect. Pist. Germen superior, roundish; style simple, projecting beyond the stamens; stigma cloven, thickish. Peric. Berry roundish, of two cells. Seeds several, kidney-shaped. Receptacles convex, fixed on each side of the partition.

Ess. Ch. Corolla tubular; its orifice closed by the beards of the filaments. Berry of two cells, with many seeds.

The species of this genus have been very imperfectly explained in many of the works of Linnaeus. The fourteenth edition of *Syst. Veg.*, edited by Murray, contains eleven, of which the first and fifth are one and the same plant, no *Lyceum* at all, but the *Scriffa* of Justen; see Willd. Sp. Pl. v. 1. 1061; see also our article DYONIA. The seventh and eighth also are but one species, *boerhaavi-jolium* of Linn. Suppl. and the eleventh, *capfulare* of Sp. Pl. 278, appears, by the Linnaean herbarium, to be a new description of *Hydrolea*; called *glabra* in the Banksian collection, where is the other half of the very same specimen, of which a part was sent to Linnaeus by Müller, who received it from New Spain. Seven, therefore, only of the above number remain, to which three are added from Thunberg, in Willdenow. The latter, therefore, is correct in his enumeration, except with respect to the *capfulare*. But Thunberg has given more recent illustration of his own new species in the ninth volume of the Linnaean Society's Transactions, with plates. We shall briefly describe the whole, with an additional species from Michaux.

1. *L. afrum*. African Box-thorn. Linn. Sp. Pl. 277. (*L. folis hircaribus*; Trew. Ehret. 4. t. 24. Jasminoides aculeatum humile, halimi minoris folio, flore majori violaceo, fructu crassiore, per maturitatem flavescente; Mich. Gen. 224. t. 105. f. 2.)—Leaves clustered, linear, tapering at the base. Branches straight, ending in a spine.—Native of the north of Africa, and some parts of Spain. It has been long cultivated in the greenhouses of the curious, but has little to attract general admiration. The stem is shrubby, rigid, much branched; each branch ending in a stiff straight spine. Leaves linear, bluish, entire, various in length and breadth, many together in lateral clusters, smooth, rather glaucous and fleshy. Flowers solitary, purple, about an inch long, drooping; on simple stalks, usually twice or thrice as long as the calyx. Linnaeus cites Micheli very erroneously,

erroneously, which Willdenow, not turning to the book, has omitted to correct.

2. *L. rigidum*. Rigid Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 153. t. 14.—Leaves clustered, linear. Branches straight, ending in a spine. Flowers nearly sessile.—Gathered by Thunberg near Cape Town, flowering in July and August. It differs from the former chiefly in having the *flowers* nearly sessile, with a much shorter and broader *corolla*. The *leaves* also are narrower.

3. *L. ruthenicum*. Tartarian Box-thorn. Murr. Comm. Gott. for 1779, p. 2. t. 2. Ehrh. Exsicc. n. 4. (*L. tataricum*; Pall. Ross. v. 1. fasc. 1. 78. t. 49.)—Leaves linear, clustered, from spinous buds. Branches elongated, pendulous.—Native of Siberia and Tartary. The *branches* are long, slender, pendulous, compound, with a pale smooth bark, and a solitary prominent spine from each bud. *Leaves* linear, bluntish, tapering at the base, scarcely more than three or four in each cluster. *Flowers* drooping. *Corolla* funnel-shaped, about half an inch long, pale purple. *Calyx* somewhat two-lipped. This is smaller in all its parts than the following.

4. *L. barbarum*. Willow-leaved Box-thorn, or Blue Jasmine. Linn. Sp. Pl. 277. Schkuhr. Handb. v. 1. 147. t. 46.—Leaves lanceolate, solitary or clustered, very unequal. Spines axillary. Branches elongated, pendulous.—Native of Europe, Asia, and Africa, very hardy with us, and long cultivated for bowers and trellises, being a rambling shrub of very luxuriant growth, though no great beauty. Its *flowers* are purple. *Berries* of an orange-red. The Chinese variety, distinguished by gardeners, and figured by Duhamel, differs scarcely in any thing. The *calyx* is occasionally three or five-cleft, and somewhat two-lipped, in that as well as the ordinary kind. This plant blossoms from May to the very end of autumn, bearing flowers and fruit together in abundance.

5. *L. tetrandrum*. Four-cleft Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 154. t. 15. Linn. Suppl. 150.—Leaves obovate, clustered. Branches straight, angular, ending in a spine. Flowers four-cleft.—Native of the Cape of Good Hope, towards the sea, flowering in June. Thunb. A rigid, branched, smooth *shrub*, with the habit of the first two species, but very small, fleshy, obovate *leaves*, and small, funnel-shaped, short, white *flowers*, whose *corolla* is four-cleft, and *stamens* four only.

6. *L. cinereum*. Grey-barked Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 154. t. 16.—Leaves lanceolate, clustered, nearly equal. Branches ending in a spine. Flowers on very short stalks.—Found at the Cape of Good Hope by Thunberg. He describes the *stem* as round, striated, smooth, grey, much branched, zigzag, and erect; the *branches* alternate, slender, elongated, each terminating in a sharp spine. *Leaves* smooth, acute. *Flowers* axillary, solitary, on stalks scarcely longer than the calyx, and not half the length of any of the leaves.

7. *L. horridum*. Succulent-leaved Box-thorn. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 154. t. 17.—Leaves obovate, fleshy, smooth. Branches numerous, ending in a spine. Flowers on very short stalks.—Grows in maritime situations at the Cape, flowering from September to November. Thunb. The *stem* is three feet high, rigid, abounding with short spinous *branches* in every direction. *Leaves* from three to seven in a cluster, not half an inch long, sessile, thick, smooth; flattish and green above; convex, white, and marked with a green line, beneath. *Flowers* solitary, small, on short stalks. They are represented in the figure with four segments only, though of this nothing

is said in the character or description. If it be corrected, the present species comes very near the fifth.

8. *L. europæum*. European Box-thorn. Linn. Sp. Pl. ed. 1. 192. Mant. 47. (*Jasminoides aculeatum*, *falciis folio*, *flore parvo*, *ex albo purpurascens*; Mich. Gen. 224. t. 105. f. 1.)—Leaves obovate, oblique, clustered. Spines lateral and terminal. Stem erect.—Native of the south of Europe; hardy in our gardens, flowering all summer long. Linnæus confounded this, in the second edition of *Sp. Pl.*, with his *barbarum*, from which it is very distinct. The *stem* and *branches* are firm and upright. *Leaves* obovate, oblique or twisted, sometimes minutely downy. *Corolla* paler, longer, and more slender. There is no prominent green line, running down the branches from each bud, as in the *barbarum*.—The present is *Rhamnus primus* of Clusius and Dodonæus; see Ger. em. 1334. fig. 1.

9. *L. boerhaavifolium*. Glaucon-leaved Box-thorn. Linn. Suppl. 150. (*L. heterophyllum*; Murr. Comm. Gott. for 1783. p. 6. t. 2. *Elætria halimifolia*; P'Herit. Stirp. fasc. 1. 45. t. 23.)—Leaves ovate, oblique, acute, glaucous. Spines lateral. Flowers in terminal clusters.—Native of Peru. This is a very pretty *shrub*, with spines accompanying the buds on the stem and older branches; the young shoots are unarmed, slender, spreading horizontally. *Leaves* scattered, stalked, about an inch long, ovate, entire, glaucous, smooth. *Flowers* several together, in a cluster, or short panicle, at the end of each branch, purplish, very fragrant. *Calyx* hemispherical, with five sharp equal teeth. *Corolla* rather short and funnel-shaped, with long projecting *stamens* and style; the former hairy at the base. The *stigma*, according to P'Heritier, is sometimes capitate, sometimes cloven, or of two valves, which must surely be owing to the different periods of its age.

10. *L. barbatum*. Fringed Box-thorn. Murr. in Syst. Veg. ed. 14. 228. Thunb. Prodr. 37. Tr. of Linn. Soc. v. 9. 155. (*L. inerme*; Linn. Suppl. 150.)—Leaves ovate, smooth. Branches zigzag, without spines. Panicles axillary.—Gathered by Thunberg at the Cape of Good Hope, on little hills about Cape-town and elsewhere, flowering in August and the following months. "The *stem* is shrubby, quite smooth, two feet high or more, with alternate, spreading, zigzag, rugged, grey *branches*. *Leaves* opposite, stalked, ovate, pointed or bluntish, entire, smooth, green above, pale beneath, an inch or more in length. *Foot-stalks* three quarters of an inch long. *Flowers* axillary, panicled, on capillary stalks. *Stipulas* or *bracteas* fringed with white. *Berry* two-lobed, compressed, abrupt, with two furrows and two cells." Thunb.—Of this we have neither seen a specimen nor figure, nor has it yet appeared in any English garden.

11. *L. carolinianum*. Carolina Box-thorn. Mich. Bo-real-Amer. v. 1. 95. Donn Cant. ed. 5. 47.—Leaves spatulate-oblong. Branches without spines. Flowers four-cleft.—Native of the rushy salt-marshes of Carolina, Georgia, and Florida. Said to have been brought to England in 1806. The *stem* is shrubby. *Leaves* narrow. *Flowers* blueish, four-cleft, with four *stamens*.

LYCUM, in Gardening, contains plants of the shrubby exotic kind, of which the species cultivated are the African boxthorn (*L. afrum*); the willow-leaved boxthorn (*L. barbarum*); the European boxthorn (*L. europæum*); and the Tartarian boxthorn (*L. tataricum*).

The second sort affords several varieties. The first has a shrubby stalk seven or eight feet high, sending out several irregular branches, armed with strong spines, and furnished with short thick leaves: the flowers which come out from the side of the branches are small and purple. They appear

in July and August, but do not produce seeds in this climate.

The second has the stalk four or five feet high, sending out many irregular branches, covered with a very white bark, and armed with a few short spines; the leaves are about three inches long, and one inch broad in the middle, alternate, pale green. The flowers appear in May, and are succeeded by small round berries that ripen in the autumn, when they become as red as coral.

The third rises with weak irregular diffused branches to a great height, requiring support; some of these branches have in one year been upwards of twelve feet long; the lower leaves are more than four inches long, and three broad in the middle; they are of a light green and a thin consistence, placed without order on every side of the branches. As the shoots advance in length, the leaves diminish in size, and towards the upper part are not more than an inch long and a quarter of an inch broad; fitting close to the stalks on every side. The flowers come out singly at every joint towards the upper part of the branches, on short tender peduncles, and are of a pale colour with short tubes; the brins are spread open, broader than either of the former sorts, and the style is considerably longer than the tube of the corolla.

Method of Culture.—All these plants may be increased by seeds, cuttings, or layers.

The seeds should be sown in the autumn soon after they are ripe, in pots, being plunged into an old tan-bed in winter, and covered with the glasses in frosty weather; but in mild weather be open to receive moisture; in the following spring the pots should be plunged into a moderate hot-bed, to bring up the plants, which must be inured to bear the open air as soon as the danger of frost is over, and when they are three inches high, be shaken out of the pots, and each planted in a small separate pot filled with loamy earth, being placed in the shade till they have taken new root, when they may be removed to a sheltered situation, to remain till the autumn, when they should be either removed into the greenhouse, or placed under a hot-bed frame, to shelter them from hard frost. They must at first be kept in pots, and treated in the same way as myrtles, and other hardy greenhouse plants; but when they are grown strong, a few of them may be planted out in the open ground in warm situations, where they stand moderate winters, but are commonly destroyed by hard frosts.

The cuttings should be made from the young shoots, and be planted in a shady border in July, being duly watered; and when they have taken root, be treated in the same manner as the seedling plants. This is the usual mode of increasing them, as some sorts never produce seeds in this climate.

In the third sort the cuttings should be planted in the spring, in an eastern border; and the plants should not be removed till the autumn, when they may be planted to cover walls, as the branches are too weak to support themselves.

The third variety may also be increased by dividing and planting its creeping roots.

The layers must be made from the young branches, and be laid down in the spring; and when rooted in the autumn, taken off, and managed as in the other methods.

The hardy sorts afford variety in warm situations in the open ground, and the other sorts among greenhouse collections.

Lycium, in the *Materia Medica*, the name of a fruit called by the French *baye d'Adignon*, the Avignon berry, and by many authors the *pyracantha*. The shrub which

produces it is the *lycium five pyracantha* of Gerrard. (See *LYCIUM, supra*) The fruit is about the size of a grain of wheat, and is not round, but of an angular form when dried, sometimes of three, sometimes of four angles, and sometimes dented in at one end like a heart. It is of a yellowish-green colour, and of a bitter and astringent taste. It should be chosen fresh dried, and large. There was formerly a rob, or inspissated juice made from these berries, much in use in medicine; but this was generally adulterated with a rob made of the berries of the woodbine, privet, sloe, or other shrub, and is now quite out of use. The dyers in France and Holland use it for a yellow; and the Dutch have another use for it, which is, that they boil it in alum-water, and mixing it in whitening, form it into twisted sticks, which they sell to the painters in water-colours, under the name of *fil de grain*.

LYCOCTONON. See *ACONITE*.

LYCODONTES. See *BURONITE*.

LYCOGALIA, in *Botany*, so named by Micheli, from *lyx*, a wolf, and *gala*, milk, a genus of the fungus tribe, whose internal appearance and substance, in an early state, are like a mass of thick cream. It is included under *Mucor* by Linnaeus, Schreber, and others. Perf. Syn. 157. Mich. Gen. 215. t. 95. Albert. and Schwein. 83. (*Reticularia*; Bulliard Fung. v. 1. t. 476. f. 1—3.)—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Case roundish, membranous, smooth, lodging a mass, originally pulpy and deliquescent, finally powdery intermixed with distant internal fibres.

1. *L. argenteum*. (*L. griseum majus*; Mich. Gen. 216. t. 95. f. 1. *Reticularia Lycopodon*, var. 2; Bull. Fung. v. 1. 95. t. 476. f. 1. *Mucor lycogalus*; Bolt Fung. v. 3. 133. t. 133. f. 2.)—Cushion-shaped, somewhat hemispherical, naked, even of a silvery white.—Found upon rotten wood in autumn.—About an inch or more in diameter, brown and pulpy when young, of a brilliant white when arrived at maturity, discharging, by one or more irregular accidental openings, a mass of rich dark saffron-coloured powder.

2. *L. turbinatum*. (*Reticularia Lycopodon*, var. 3; Bull. v. 1. 95. t. 476. f. 2.)—Top-shaped, naked, even, pale brown. Found in similar situations, though rarely. But half the size of the former, at most, and furnished with a kind of short stalk, which gives it a pear-shaped figure. Hence Persoon was induced to make this a distinct species, though he appears to have known it merely by the account of Bulliard. The latter says it is pellucid when young.

3. *L. punctatum*. (*Reticularia Lycopodon*, var. 4; Bull. v. 1. 95. t. 476. f. 3.)—Aggregate, globose, dotted, greyish.—Found on rotten wood. Nearly as big as the first, but more globose, and of an ashy-grey; its surface dotted all over with minute points.

4. *L. atrum*. Albert. and Schwein. n. 233. t. 3. f. 3.—Cushion-shaped, black. Its powder is intermingled with branched, tree-like, radiating fixed threads. This, not mentioned by Persoon, is described by the above authors of the *Confessus* of Fungi, growing near Nistie in Upper Lusitania, as found upon fir trees from April to June, and more sparingly in October and November. It is the size and shape of the first species; white in the beginning, then of a dirty yellow, afterwards reddish-brown, and finally black. This fungus is remarkable for leaving, as it were, a skeleton of branched black fibres, radiating from a centre, when the coat and powder are gone.

5. *L. minutum*. Perf. n. 4. (*L. minuta*; Perf. Obs. Mycol. fasc. 2. 26. *L. globosum*, granis pili magnitudine, ære costis colore; Mich. Gen. 216. t. 95. f. 2. *Lycopodon*

don epidendrum; Linn. Sp. Pl. 1654. Hudf. 645. With. v. 4. 385. Sowerb. Fung. t. 52. Bolt. Fung. v. 3. 110. t. 119. f. 1. Mucor; Schæff. Fung. t. 193.)—Aggregate, globose; at first scarlet; then brown, with rose-coloured powder.—Common on the trunks of trees, after rain, in summer and autumn. Its vivid vermilion or scarlet hue, when young, is very striking. In decay it turns brown or black. Mr. Sowerby has exhibited, in his t. 400. f. 2, 3, what he esteems a luxuriant variety of this, but which seems to us a distinct species, being much larger, confluent, pale pink and veiny, soon turning quite black. In an early state it looked like the intestines of a fowl.—*Lycoperdon pisiforme* of Linnæus is judged by Persoon to be only a roughish-coated variety of this *Lycogala minutum*.

6. *L. conicum*. Pers. n. 5.—Scattered, conical; at first red; then purplish-violet.—Found, very rarely, on the rotten trunks of trees. About one or two lines high, exactly conical, but obtuse, clothed with little scattered fibrous granulations. Powder of a violet red. Persoon.

LYCOIDES, a term used by medical writers to express the disorders which arise in the human body by a long retention of the seed. These are sometimes madness, and very often dangerous quinities and swellings, and inflammations about the neck and throat. If we consider the natural tendency of the disorders of this kind to affect the neck, and the remarkable swelling of the necks of bucks, and some other animals at rutting time, it may give some rational hints towards understanding the alteration of the voice in boys who arrive at puberty.

Blancard derives the word *lycoides*, from *λύκος*, *lupus*, and *ειδος*, *forma*, from a supposition that wolves are subject to this disorder.

LYCOMING, in *Geography*, a county of America, in the N.W. part of Pennsylvania, bounded N. by the state of New York, and W. by Alleghany county; 150 miles long and 86 broad, being the largest in the state. The north and west parts are unsettled. It is divided into 10 townships, and contains 5414 inhabitants.—Also, a creek, which runs south, and discharges itself into the W. branch of Susquehanna, a few miles W. of Loyalsock creek.

LYCOPERDASTRUM, in *Botany*, Baitard Puff-ball, Mich. Gen. 219. t. 99. See *SCLERODERMA*.

LYCOPERDOIDES, Mich. Gen. 219. t. 98, a genus consisting of three species of fungi, very unlike each other. The first has a stout thick many-rooted stem, four inches high, and is the *Scleroderma tinctorium* of Persoon, Syn. 152. The others are subterraneous productions, akin to the *Lycoperdon cerinum* of Linnæus.

LYCOPERDON, so called by Tournefort, from *λύκος*, a wolf, and *πίσος*, to explode backwards, this author having certainly improved the old foolish name, *Crepitus lupi*, by making it less generally intelligible. We do not presume to account for this curious appellation. The French call the fungus to which it is applied *Vesse-loup*, or Wolf-bladder; the English *Puff-ball*; and the Germans *Bössl*; from which last Linnæus contrived the barbarous name *Bovista*. Linn. Gen. 569. Schreb. 770. Mur. Mill. Dict. v. 3. Pers. Syn. 130. Juss. 5. Tourn. t. 331. Lamarek Illustr. t. 887.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Cafe caulescent, arising irregularly at the top, clothed with scaly or pointed warts.—(The powder or seed is greenish.) Persoon.

The author last mentioned defines 14 species of this genus, very properly restricting it to such fungi as answer to the above character, and excluding the starry puff-balls, (see *CEASTRUM*); as well as the *Tuber*, the *Scleroderma*, and

some others which Linnæus comprehended under his *Lycoperdon*. Examples are

L. giganteum. Pers. n. 1. Batf. h Fung. t. 165. (*L. maximum*; Schæff. Fung. v. 4. 130. v. 2. t. 191. *L. Bovista*; Bulliard t. 447. *L. Proteus*; Sowerb. Fung. t. 332, two upper figures.)—This is often found as big as a man's head, in dry upland pasture, in various parts of England and the south of Europe. When the upper part, and the whole powdery contents, are blown away, the spongy base, with a thin torn edge, remains for a considerable time. The root is small, but tough.

L. pyriforme. Pers. n. 12. Schæff. Fung. v. 4. 128. v. 2. t. 185. (*L. ovoideum*; Bulliard t. 435. f. 3.)—Found on rotten stumps in beech woods in autumn. It is an inch and a half high, and an inch broad, tapering at the base, and pointed at the top, of a dirty brownish-white.

L. gossypinum. Pers. n. 14. Bulliard t. 435. f. 1.—Found on rotten wood in France. A pretty species, about one-fourth of an inch in diameter, globose with a short taper base, all over white or pale grey, and covered as it were with a fine down or cottony subulance.

LYCOPERSICON, from *λύκος*, a wolf, and *πέρσιον*, a peach, the Tomato, or Love-apple, *Solanum Lycopersicum* of Linnæus. This fruit is valued for its grateful acidity in Italy, Spain and Portugal, where it makes a principal ingredient in many soups and other dishes, being moreover supposed to possess a stimulating, or aphrodisiac property. Raised in England, its flavour is more insipid, and its qualities not in any respect, as far as we have heard, remarkable; except that few stomachs can bear it in any great quantity. The fruit is best fried in slices, peppered and salted, as a sauce for game or any roast meat.

LYCOPHRON, in *Biography*, son of Periander, king of Corinth, flourished about five hundred and fifty years before the Christian era. The murder of his mother Melissa, by his father, had such an effect upon him, that he resolved never more to speak to him. This resolution was strengthened by their uncle Proclus, king of Epidaurus, who took Lycophron and his brother under his protection. When the infirmities of Periander obliged him to look for a successor, Lycophron, who was then in the island of Corcyra, refused to come to Corinth while his father was there, and he was induced to promise to settle in that city, only on condition that his father would come and dwell on the island which he left. So fearful, however, were the Corcyrians of the tyranny of Periander, that they killed the son to prevent the meditated exchange from taking place.

LYCOPHRON, a famous Greek poet and grammarian, was born at Chalcis, in Eubœa, and flourished about three hundred years before the Christian era. He was one of those poets who lived in the reign of Ptolemy Philadelphus, and who from their number obtained the name of Pleiades. According to Ovid he was slain by an arrow. He was author of several tragedies, of which the titles of twenty have been preserved; but the only work that has come down to us, is a very singular poem, entitled "Alexandra," or Cassandra, the subject of which is a series of predictions feigned by him to have been uttered by that daughter of Priam. This poem contains 1474 verses, the obscurity of which has procured the epithet of "Tenebrosus" to its author. It is a mixture of prophetic effusions, supposed to have been delivered by Cassandra during the Trojan war. The best editions are that of Bank, 1516, enriched with a commentary by Tzetzes; that of Canter, 1596; and that of our countryman, archbishop Potter, in 1702.

LYCOPITHELMUS, the *wolf's eye-stone*, a name given by some authors to such pieces of agate, or any other

semi-pellucid stone, as happen to have circular spots in them, resembling in colour the eye of that animal.

LYCOPODIODES, in *Botany*. See the following article.

LYCOPODIUM, from *λυκος*, a wolf, and *πους*, the foot, from the incurved, and often finger-like, shape of the spikes or extreme branches. Club-moss, or Wolf's-claw.—Linn. Gen. 561. Schreb. 753. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1108. Swartz. Fil. 174. Brown Prodr. Nov. Holl. v. 1. 165. Juss. 12. Lamarck Illustr. t. 872. Michaux Boreal-Amer. v. 2. 282. Dill. Musc. 441. (Lycopodioides; Dill. Musc. 462. Selago; ibid. 435. Selaginoides; ibid. 460.)—Class and order, *Cryptogamia Musci*, Linn. *Crypt. Miscellanea*, Schreb. *Crypt. Filices*, Smith. *Crypt. Lycopodineæ*, Swartz.—Nat. Ord. *Musci*, Linn. Dill. *Musci spurii*, Juss. *Lycopodineæ*, Brown.

Eff. Ch. Capsules axillary, sessile, naked, mostly solitary, of one cell; some kidney-shaped, of two elastic valves, and full of fine powder; others two or three-lobed, of two or three valves, lodging from one to six globose bodies.

This beautiful and ample genus, one of the most elegant, with respect to habit, in the whole vegetable kingdom, holds as it were an intermediate place between the ferns and mosses. Some botanists have therefore been most inclined to refer it to the one tribe, others to the other. Its habit, most like the mosses, does yet by no means strictly accord with that order; and their fructification, being now well understood, separates them distinctly from *Lycopodium*, whose nature in that respect is almost totally in the dark, agreeing so far with ferns. The seeds of the latter, however produced, agree as nearly as can be with the powder found in the compressed or kidney-shaped capsules of the genus in question, which powder moreover has been likewise proved, by experiment, to be real seed. But the globular bodies found in peculiar capsules upon *L. denticulatum* and other species, proved themselves seeds by germinating, according to Brotero, Tr. of L. Soc. v. 5. 162, yet such species are furnished besides with what seems to be the genuine fruit of the genus. In this difficulty Professor Swartz and Mr Brown have prudently contented themselves, in the generic character, with mentioning these two kinds of apparent capsules and seeds, without positively asserting either to be such.

Joseph Fox, a poor journeyman weaver of Norwich, is the first person upon record who ever raised plants of *Lycopodium Selago* from the dust of the kidney-shaped capsules; see Tr. of Linn. Soc. v. 2. 314, where Mr. Lindsay's account of having succeeded equally well with the dust of *L. cernuum* in Jamaica, is also to be found. Sprengel cites the authority of Professor Willdenow in confirmation of this. We cannot but admit therefore that this dust, so exactly resembling the known seed of ferns, is real seed. This is the *Pulvis Lycopodii*, formerly kept in the apothecaries shops, on account of some reputed qualities long since disbelieved. It is still used in Germany to produce the appearance of lightning upon the stage; for being very light and highly inflammable, it takes fire instantaneously, with a sort of hissing explosion, while floating in the air. The dust of *L. clavatum* is collected and sold on the continent, for this purpose. With respect to the globular bodies, whose bulk is beyond all measure greater than that of these minute seeds, it is impossible to doubt the assertion of Professor Brotero, who in the fifth volume of the Transactions of the L. Soc. describes their germination, radicle, cotyledons, &c.; so that we must allow the existence of two kinds of seed on the same plant. The same phenomenon has been suspected in the genera *Fucus* and *Conserva*, though bota-

nists have been so justly cautious of admitting it, that they have not dared to trust their own eyes. Perhaps the actual existence of the fact in *Lycopodium*, may sanction our belief of it in these other instances. The difference however between these two kinds of seeds in *Lycopodium* is far more essential than Professor Sprengel seems to insinuate, when he says it "only proves that the capsules of several species of this genus are of two different shapes." (Crypt. 195, English translation.) Nothing can be greater than the apparent difference betwixt the two kinds of seeds themselves, which is such as to overset all analogy hitherto known. An idea advanced in Engl. Bot. v. 16. p. 1148, that the kidney-shaped capsules may be abortive ones, can hardly be admitted; for although we hear of no experiment made with the contents of the two different kinds of capsules from the same individual plant, (which if plants could be raised from both, would be truly an *experimentum crucis*;) yet the kidney-shaped capsules of the species in question, *L. Selaginoides*, are too precisely like those from which vegetating seeds have been obtained, to allow of a doubt concerning them. We ought not to omit that Dillenius first observed these different kinds of seeds in *Lycopodium*, and has founded upon them the different genera into which he has divided it, as quoted among the synonyms above.

The 14th edition of *Syst. Veg.* contains 29 species of *Lycopodium*, six of which are British. Professor Swartz defines 65; exclusive of the Linnæan *nudum*, which he establishes as a distinct genus, by the name of *Psilotum*; as well as of several others, which he finds mentioned in books, but could not satisfactorily ascertain.—Fifteen species have axillary sessile capsules, all uniform, of two valves, containing the above-described powdery kind of seeds. The remaining 50 bear their capsules in terminal spikes, each capsule being accompanied by a peculiar scale or bractea, generally toothed or fringed, totally unlike the leaves, and mostly of a paler or more tawny colour. Of these 50, 26 have the same kind of capsules and seeds as the above 15, and no other; one, (*L. Selaginoides*, Engl. Bot. t. 1148.) has, besides such capsules, very remarkable four-lobed ones, of two three-lobed valves, and containing four globose white seeds. The remainder have kidney-shaped as well as roundish, rarely three-lobed, capsules, either intermixed in the same spike, or the former are in the upper part, the latter in the lower. By this statement it appears, that no known species is without the kidney-shaped compressed capsule, bearing the minute dust-like seed, analogous to that of ferns; the larger globose seed being, as it seems, more of an adventitious nature.

Examples of the axillary species are,

L. linifolium. Linn. Sp. Pl. 1563. Sw. n. 1. (Selago linearis foliis; Dill. Musc. 440. t. 57. f. 5.)—Leaves alternate, remote, lanceolate.—Native of South America and the West Indies. Taken up by Dillenius from Plumier, who in his *Filices*, t. 166. f. C, C, gives an original plate of this species, which no other botanist appears to have seen. The root is fibrous. Stems seemingly pendulous, above two feet long, slender, slightly branched, leafy throughout. Leaves scattered, half an inch at least distant from each other, often near two inches long, entire, taper-pointed, somewhat ovate and twisted at the base. Capsules axillary, solitary, kidney-shaped. No other known species can vie with this in the size and distance of its leaves.

L. guineoides. Linn. Suppl. 448. Sw. n. 4.—Leaves three in a whorl, imbricated, ovate-lanceolate, obtuse, entire. Branches elongated.—Gathered in the island of Mauritius by Sonnerat or Commerçon, and given by Thouin to the younger Linnaeus. No other botanist seems to have seen the plant. It appears to be very tall, with the habit of the former,

former, but differs essentially in its much closed and whorled leaves, not half an inch long, blunt and concave, without rib or vein; the upper ones very gradually shorter and more ovate, with solitary, palish, axillary, roundish, slightly reniforme, capsules.

L. Selago. Fir Club-moss. Linn. Sp. Pl. 1565. Engl. Bot. t. 233. Sw. n. 12. Fl. Dan. t. 104.—Leaves scattered, in eight rows, somewhat imbricated, lanceolate, acute, rather concave. Stem forked, erect, level-topped.—Native of rather moist mountainous heaths; the only British species of this first section. The stems are about a span high, beset with dark, shining, fir-like leaves. Capsules small, brownish-yellow.

The spiked species are not only numerous, but, in many instances, remarkable for size and beauty. The British ones are *inundatum*, Linn. Sp. Pl. 1565. Engl. Bot. t. 239; *alpinum*, ib. 1567. E. Bot. t. 234;—*annotinum*, ib. 1566. E. Bot. t. 1727; and the common *clavatum*, ib. 1564, E. Bot. t. 224.—This last grows abundantly on dry mountainous heaths, creeping on the ground to the extent of several feet; the fruit-bearing branches only being erect. These bear one, two or three, finger-like dense spikes of ovate, taper-pointed, membranous-edged, imbricated bracts, each with an axillary solitary brown capsule.

Of the foreign ones none is more striking than *L. Phlegmaria*. Linn. Sp. Pl. 1564. (*L. erectum dichotomum, foliis cruciatis, spicis gracilibus*; Dill. Musc. 450. t. 61. f. 5.—Leaves ovate or heart-shaped, entire; the lower ones four in a whorl. Spikes thread-shaped, forked.—This grows in various parts of the East Indies, as well as in the isle of Bourbon. Mr. Menzies gathered our specimen in Otaheite. It is 18 inches or more in height, slightly forked or branched, clothed with numerous shining leaves, not so regularly whorled, at least the upper ones, as Dillenius found them. The long, terminal, slender, forked spikes, with their little roundish bracts, scarcely broader than the accompanying capsules, are very singular.

Among the species with two sorts of capsules is

L. flabellatum. Linn. Sp. Pl. 1568. (*Lycopodioides dentatum erectum filicinum, caule tereti ramosissimo*; Dill. Musc. 468. t. 65. f. 5. Muscus squamosus erectus; Plum. Fil. t. 43. Amer. t. 24.)—Leaves two-ranked, ovate, oblique, fringed at the base, accompanied by a double row of smaller imbricated ones in front. Stem round, repeatedly branched, flattened above.—The figures of this species, which is found in the West Indies, give but an inadequate idea of its beauty. Its flat fan-like shape, and the exquisitely neat arrangement of the innumerable little shining leaves, give it a peculiar and striking aspect. The spikes are small, and sparingly produced. Root fibrous. Whole plant from one to two feet high.

LYCOPOLIS, in *Ancient Geography*, viz. the city of the Wolves, an ancient town of Upper Egypt, in the Thebais, situated on the western side of the Nile; so called, because extraordinary worship was paid here to wolves, which, according to Diodorus Siculus, drove back the Ethiopians when they invaded Egypt, and pursued them to Elephantina, on the borders of Ethiopia. This city is supposed to have stood where the present town of Monfalut now stands.

LYCOPSIS, in *Botany*, so called by Pliny, being also the *wolf*; of Dioscorides, owes its derivation to *lycus, a wolf*, and *opsis, a face, or countenance*, from the circumstance of the flowers being ringent, and having the appearance of a grinning mouth; the herbage is also furnished, says Ambrosinus, with a sort of rigid hairiness similar to the coat of a wolf. Linn. Gen. 78. Schreb. 103. Willd.

Sp. Pl. v. 1. 779. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 220. Ait. Hort. Kew. ed. 2. v. 1. 297. Juss. 131. Lamarck Illustr. t. 92. Gærtn. t. 67.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Asperifolia*, Linn. *Borragineæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five, oblong, acute, spreading, permanent segments. *Cor.* of one petal, funnel-shaped; tube cylindrical, bent in a curve; limb five-cleft half way down, obtuse; mouth closed, with five convex, prominent, uniting scales. *Stam.* Filaments five, very small, placed at the curve of the tube of the corolla; anthers small, covered. *Pist.* Germens four, superior; style thread-shaped, the length of the stamens; stigma obtuse, cloven. *Peric.* none, except the very large, inflated calyx. *Seeds* four, rather long.

Eff. Ch. Corolla with a curved tube, its mouth closed with convex scales.

Linnaeus was acquainted with seven species of *Lycopsis*, to which Willdenow has added two more, *L. ciliata*, and *obtusifolia*. This genus is particularly marked by the tube of the flowers being curved: indeed this circumstance is considered by Linnaeus and Willdenow as a sufficient essential character. The following species will serve to illustrate the genus.

L. pulla. Dark-flowered Bugloss. Linn. Sp. Pl. 198. Jacq. Austr. t. 188.—Leaves entire. Stem erect. Calyx, when in fruit, inflated, pendulous.—Found in fields and by road-sides in Tartary and Germany, where it flowers from the beginning of May to July.—Root perennial, of nearly a finger's thickness, long, blackish. Stem about a foot high, roundish; simple below; dividing upwards into flowering branches. Leaves alternate, sessile, soft, thickish, pale green. Flowers solitary; petals smooth, dark purple or nearly black, the tube reddish at its base, the limb marked with five sunk dots at the bottom. Seeds roundish, somewhat rugose, sticking to the pendulous and swelling calyx.

L. arvensis. Small Bugloss. Linn. Sp. Pl. 199. Engl. Bot. t. 938. Curt. Lond. fasc. 5. t. 17. Fl. Dan. t. 435.—Leaves lanceolate, bristly. Calyx, when in flower, erect.—Very common in fields and waste places all over England. It flowers in June and July.—The whole plant is hispid. Stem round, angulated, erect, branched. Leaves oblong heart-shaped, embracing the stem. Clusters in pairs, terminal, leafy. Flowers small, of a lively blue colour, with a white eye. Seeds angular, rugose, tuberculated. The juices of this plant are mucilaginous, like those of Borage.

LYCOPUS is said to be derived from *lycus, a wolf*, and *pus, a foot*, though we are perfectly incompetent to trace the origin of such a derivation. Linn. Gen. 15. Schreb. 20. Willd. Sp. Pl. v. 1. 120. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 29. Ait. Hort. Kew. ed. 2. v. 1. 47. Brown. Prod. Fl. Nov. Holl. 500. Tournef. t. 89. Juss. 111. Lamarck Illustr. t. 18.—Class and order, *Diandria Monogynia*. Nat. Ord. *Pericillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, cloven half way down into five, narrow, acute, segments. *Cor.* of one petal, rather unequal; tube cylindrical, the length of the calyx; limb obtuse, spreading in four, nearly equal divisions; the upper one broader, emarginate; the lower smaller. *Stam.* Filaments two, generally longer than the corolla, inclining to the upper segment; anthers small. *Pist.* Germen superior, four-cleft; style thread-shaped, straight, as long as the stamens; stigma cloven, reflexed. *Peric.* none, except the calyx containing the seeds in its bottom. *Seeds* four, roundish, bluntish.

Eff. Ch. Corolla four-cleft; one of its lobes notched. Stamens distant. Seeds four, naked, blunt.

1. *L. europæus*. Water Horehound. Gypsywort. Linn. Sp. Pl. 30. Engl. Bot. t. 1165. Curt. Lond. fasc. 3. t. 2. —Leaves very deeply serrated.—Found abundantly on the banks of pools and ditches, in a sandy soil, flowering in July and August.—*Root* perennial. *Stem* square. *Leaves* opposite. *Flowers* white, many in a whorl. *Seeds* four, obovate, blunt, square, furrowed.—The whole herbage is inodorous, though the flowers are sometimes sweet-scented. It varies occasionally in having deeply pinnatifid leaves, more or less hairy: indeed they are scarcely ever quite smooth. Dr. Smith remarks that “the glandular dots, form of the corolla, and whole habit shew the affinity of this plant to *Plantago*,” but he thinks that the seeds would serve sufficiently to distinguish it without adverting to the number of its flaments.

2. *L. exaltatus*. Italian Water Horehound. Linn. Suppl. 87. Willd. n. 2. Sm. Pl. Græc. Sibth. v. 1. g. t. 12.—Leaves pinnatifid, toothed. Calyx four or five-cleft—A native of Italy, and also of Greece in Lupadia and Bithynia, flowering in the summer.—*Root* perennial, creeping. *Stem* erect, from four to six feet high, leafy, hairy, often tinged with red. *Leaves* opposite, crossing each other in pairs, deeply pinnatifid, hairy on both sides. *Whorls* axillary, sessile, dense, many-flowered. *Bractææ* small, linear-lanceolate, acute. *Corolla* tubular, white, a little longer than the calyx, mouth hairy. *Seeds* obovate, blunt, covered with resinous dots, aromatic.

The pinnatifid variety of *L. europæus* has by some authors been confounded with the present plant; but on account of that species having a more humble stem, the segments of its leaves never toothed, and the calyx invariably five-cleft, Dr. Smith thinks they are sufficiently distinct.

3. *L. virginicus*. Linn. Sp. Pl. 30. Michaux. Boreal-Amer. v. 1. 14.—Leaves stalked, elliptical, tapering at each end, equally serrated.—A native of America, from New England to Carolina. It flowers in the autumn.—The Linnæan specimen of this species has leaves above an inch in breadth, with strong, though not deep serratures. It therefore very ill agrees with the definition in *Flora Virginica*, “Leaves lanceolate, very finely serrated,” or with Clayton’s account, “Leaves long, narrow, and grassy.” It answers, however, exactly to Michaux’s definition, “Leaves broadly lanceolate, serrated, contracted, and entire at the base.”—The flowers are numerous, in dense whorls. *Seeds* angular, each crowned with several blunt teeth.

Besides the three species above described, Mr. Brown, in his Prodrômus to the Flora of New Holland, mentions another, which he calls *australis*, with the following character, “Leaves lanceolate, pointed, serrated, downy, roughish above, glandular beneath, entire, and attenuated at the base: serratures remote, equal, very acute. Stems striated.”—This is found all over New Holland, and in Mr. Brown’s opinion is very nearly allied to *L. europæus*. Michaux has another species under the name of *uniflorus*, which is thus characterized. “Plant very small. *Root* tuberous. *Stems* simple. *Leaves* oval, obtuse, obsolete toothed. *Flowers* axillary, solitary.” This is a native of North America.

LYCOSTAPHYLÆ, *wolf’s grapes*, a name given by some of the Greek writers to the *pomum amoris*, a kind of esculent nightshade, which we have much more properly called *hyoscyamus*, the *wolf’s peach*. (See SOLANUM.) Æmilius Macer tells, that the nightshades, in general, were called by the name *morella* in his time: his words are, “herbam

quam Græci strychnum dixere, Latini morellam dicunt.” The name *morella* seems to be formed upon the word *morion*, a name given both by the Greeks and Latins to one of the sleepy nightshades, and to the male mandrake of Dioscorides, which the shepherds were fond of eating; but which brought on sleepy disorders, if taken too largely.

LYCOSTOMUS, in *Ichthyology*, the name given by Elian, and many other of the Greek authors, to the *anchovy*, called by others the *encraulus* and *encrausibolus*, and by the late writers *encrasicolus*. See *CLUVEA Encrasicolus*, and *ANCHOVY*.

LYCTOS, in *Ancient Geography*, a town situated in the interior of the isle of Crete, and not far from Gnosus to the south-east. Of this town Polybius says, that it was a colony, originally of Lacedæmonians, and the most ancient of the Cretan towns, which produced men who were, without contradiction, the bravest and most virtuous in the whole island. The priority of its existence to Gnosus and Cortyna, however, has been doubted.

LYCURGIA, *λυκουργία*, in *Antiquity*, a festival celebrated by the Spartans in memory of Lycurgus, whom they honoured with a temple, and an anniversary sacrifice.

LYCURGUS, in *Biography*, the celebrated legislator of Sparta, supposed to have been born about the year 926, was son of Eunomus, king of that country, and brother to Polydectes. He might have succeeded to the throne himself on the death of Polydectes, but knowing that the deceased king’s widow was pregnant, he publicly declared that he would only hold the crown in trust for the child, provided it should prove a son. The queen, ambitious of retaining her place and dignity, proposed to marry Lycurgus, and destroy the infant before its birth. Lycurgus took measures to prevent the completion of her wicked proposals: she was, in due time, delivered of a boy, which being brought to him, as he was sitting at the table with the magistrates, he took it in his arms, placed it in the chair of state, and exclaimed, “Here Spartans is your king.” Lycurgus faithfully discharged the duty of regent and guardian during the minority of his nephew Charilaus, and as soon as the young prince came to years of maturity, he readily resigned all authority into his hands, left Sparta, and travelled into several foreign countries, with the view of observing their laws and customs. He first visited Crete, at that time governed by the laws of Minos: these laws he studied most carefully, and contracted a friendship with Thales, whom he persuaded to settle at Sparta. He thence passed over to Asia, making observations on the principal Ionian cities, which were overwhelmed in luxury and effeminacy. Here he met with the works of Homer, which he transcribed and brought into Greece. The confusion which followed his departure from Sparta, made his presence again necessary, and he returned home at the earnest solicitations of his countrymen. Perceiving that the disorders of the state admitted no other effectual remedy than a total change of the laws and constitution, he prepared to give a new legislative system to Sparta. He took care to fortify his authority with the functions of religion, and obtained from the oracle of Delphi a declaration, that the constitution he was about to establish, would be the most excellent in the world. [For an account of his institutions see the article *LACÆDEMONIANS*.] His principal object, as a patriot, was to render his country great and respectable among surrounding nations; this he attained, and Sparta, under the laws of Lycurgus, became a nation of invincible warriors, who, for a series of years, bore the greatest sway in the affairs of Greece, and were the bulwark of their friends, and the dread of their foes. Lycurgus has been

been compared to Solon, the legislator of Athens, and it has been said that the former gave his citizens morals conformable to the laws which he had established, and that the latter had given the Athenians laws which coincided with their customs and manners. The office of Lycurgus demanded resolution, and he shewed himself inexorable and severe. The Lacedæmonians shewed their respect for this great legislator by annually celebrating a festival in his honour, at which his praises were recited, and which was observed during several ages. It is not agreed in what manner, or when he died; according to Plutarch he voluntarily put an end to his life by abstinence, while he was yet of an age to enjoy it. Lucian says he died at the age of eighty-five. The laws of Lycurgus were abrogated by Philipomen in the year B.C. 188, but the Romans very soon re-established them. Plutarch. Univer. Hist.

LYCURGUS, an Athenian orator, son of Lyeophron, flourished in the time of Philip of Macedon, and is supposed to have died about the year 328 before Christ. He studied philosophy under Plato, and oratory under Isocrates, and attaching himself to a political life rose to eminence in the state. The superintendence of the public revenue was entrusted to him, in which office he conducted himself with the strictest integrity. He was appointed one of the magistrates, and in exercising the duties of his situation, he banished all persons of a dissolute character, and made a number of very useful regulations. As he thought the higher kinds of poetry possessed superior advantages, he patronized dramatic exhibitions, and caused statues to be erected in honour of the principal tragedians. He was the friend of Demosthenes, and a zealous advocate for liberty: when Xenocrates was dragged to prison because he had not paid the tribute exacted from strangers, he liberated him and confined the farmer of the tax in his stead. Lycurgus was one of the thirty orators whom the Athenians refused to deliver up to Alexander. Some of his orations are preserved, and have been printed in Collections of the Greek Orators. Plutarch. Lempriere.

LYCUS, in *Ancient Geography*, a river of Sarmatia, S.W. of Rhodus, which discharged itself into the Euxine sea. It is mentioned by Ovi.—Also, a river, which, according to Herodotus, took its rise in the country inhabited by the Thyssagætae, and traversing that of the Mæotæ, ran into the Palus Mæotis. Ptolemy mentions this river, which is supposed to be the same with the preceding.—Also, a river of Asia, in Parthia.—Also, a river of Asia Minor, in Caria, the source of which was in mount Cadmus, and it formed a lake in Latmicus Sinus.—Also, a river in Sicily, the same with Halycus.—Also, a river of Macedonia, mentioned by Plutarch.—Also, a river of Asia Minor, in Mysia, in the canton of Pergama.—Also, a river of Asia, which proceeding from Armenia, watered the plain near the town of Hieracia, and discharged itself into the Iris.—Also, a river of Asia, in Bithynia, the same with Rhyndacus, according to Pliny.—Also, a river of Asia, in Pontus, which mixed its waters with those of the Iris.—Also, a river of Asia, in Cappadocia, according to Ptolemy, who says that it was one of the branches of the Aborus which fell into the Euxine sea.—Also, a river of Asia, in Assyria, according to Polybius and Ptolemy.—Also, a river of Asia, in Syria, near the gulf of Issus, according to Pliny.—Also, a small river of the isle of Cyprus, which had its source in the interior of the island at mount Olympus, and discharged itself into the sea to the west of Amathus.—Also, a river of Phœnicia, which ran between Byblus and Beryta, according to the Itinerary of Antonine.

LYDD, in *Geography*, a small market-town in the hundred of Langport, in the lathe of Shepway, and county of Kent, England, occupies a low situate near the south-western extremity of the county, where a point of land running out into the sea forms Dengeneys bay, which, though very open, is of great service for vessels when the wind sets violently from particular quarters. Leland says, "Lydde is counted as a part of Romney, is in myles beyond Romney town, and is a market. The town is of a pretty quantite, and the townesche men use hotes to the se, the which at this tyme is a myle of. The hole town is conteyned in one parochie, but that is very large. Ther is a place beyond Lydde, wher at a great nombre of holme trees groweth upon a banke of baches throwen up by the se: and ther they bat fowle, and kill many birdes." The church, which is a spacious edifice, consist of a nave, chancel, and aisles, with a massive tower, ornamented with pinnacles at the west end. The monuments are numerous, and among them are many brasses, chiefly for bailiffs and jurors of the town. Lydd is a corporate town by prescription, and, like Romney, of which it is a member, is governed by a bailiff, jurats, chamberlain, and commonalty. The return under the population act of the year 1800 stated the number of houses to be 204, that of the inhabitants 1303. The latter are chiefly engaged in fishing, and other maritime employments, of which smuggling is considered as forming a material branch. Lydd is 71 miles distant from London; has a small market on Thursdays, and an annual fair. The holm trees, or sea hollies, mentioned by Leland, still grow on the beach near the town.

On the point of land called Dengeneys, is a light-house, 110 feet high, erected a few years ago, in place of a more ancient one, under the direction of Mr. James Wyatt, and partly on the model of the Eddystone light-house. This point is also defended by a fort, and several ranges of barracks have been erected in the vicinity. *Beauties of England and Wales*, vol. viii.

LYDDA, in *Ancient Geography*, a town of Judæa, in the tribe of Ephraim; which was one of the three towns that Demetrius, king of Syria, compelled the Samaritans to surrender to the Jews; it was also called Diospolis.

LYDGATE, JOHN, in *Biography*, an early English versifier, and a monk of the Benedictine abbey at St. Edmund's Bury, in the reign of Henry VI. He was educated partly at Oxford, and then travelled into foreign countries to acquire the learning of the times. He was the disciple and friend of Chaucer, and was regarded as a prodigy of learning at the period in which he flourished, and is said to have been a good poet and rhetorician, geometrician, astronomer, and theologian. He opened a school in his monastery for teaching the sons of the nobility the arts of versification and composition. He was an imitator of his master Chaucer, but is reckoned among those who contributed to the improvement of the English language. His principal pieces are "The Fall of Princes," from the French of Boccaccio; "The Story of Trobe," chiefly from Guido Colonna; and "The Troy Boke," or "Description of Troy." Besides these, a list has been given of his other pieces, amounting to 251, existing in MS. in different libraries.

LYDIA, in *Ancient Geography*, first called Meonia, from Meon, king of Phrygia a c Lydia, and afterwards Lydia, from Lydus, the son of Atys, one of its kings. Bochart, who denies the existence of such persons as Meon and Lydus, derives the name Lydia from the Phœnician word *lay*, to wind, because it lay on the banks of the Mæander, a river famous for its windings, and Meonia, from a Greek translation of the Phœnician word *lay*. Lydia and Meonia are sometimes distinguished; that part where mount Tmolus stood, watered

watered by the Pactolus, being properly called Mæonia, and the other lying on the coast of Lydia. Lydia, according to Pliny, Ptolemy, and other ancient geographers, was bounded by the Mysia major on the north, by Caria on the south, by Phrygia major on the east, and Ionia on the west. But the kingdom of Lydia, as the ancients understood it, extended from the river Halys to the Ægean sea. The chief cities of Lydia were Sardis, the seat of king Cræsus, Philadelphia, formerly the second city of Lydia, Thyatira, a colony of the Macedonians, and Magnesia, seated on the Mæander. The only mountain of any note in Lydia is Sipylus. Mount Timolus was once very famous for its wine and saffron. The rivers of this country, most worthy of notice, are the Pactolus and the Cayster.

As to the origin of the Lydians, Josephus, and almost all ecclesiastical writers after him, derive them from Lud, the fourth son of Shem, an opinion founded merely on the similarity of names. Some of the ancients suppose them to be a mixed colony of Phrygians, Mysians, and Carians. Others, finding some conformity in religion between the Egyptians and Tuscans, who were a Lydian colony, conclude that they were originally Egyptians. Their fables, however, shew that they were a very ancient nation, and of their high antiquity there is ample evidence.

The Lydians began, at a very early period, to be governed by kings, whose sovereignty seems to have been despotic, and the crown hereditary.

Of their kings there are three distinct races on record, viz. the Attyadæ, so called from Atys, the son of Cotys and grandson of Manes; the Heraclidæ, or descendants of Hercules, who began to reign about the time of the Trojan war; and the Merminadæ, who began to reign not long before the Medes shook off the Assyrian yoke, of which race the first king was Gyges, and the last Cræsus. As to the character of the Lydians, they were under Cræsus, and some of his predecessors, a very warlike people; but when subdued by the Persians, and enjoined by Cyrus, according to the advice given him by Cræsus, to wear long vests, and to apply themselves to such arts only as had a natural tendency to debase their manners, and enervate their courage, they became voluptuous and effeminate, unfit for action, and wholly given up to idleness, pleasure, and diversions. The soil of this country, watered by many rivers, was very fruitful; abounding with all sorts of grain, and celebrated for its exquisite wines. It was also enriched with several mines, whence Cræsus is said to have drawn his immense wealth.

As to the religion of the Lydians, it seems to have been much the same with that of the Phrygians. They worshipped Diana, Jupiter, and Cybele at Magnesia. The customs of the Lydians were similar to those of the Greeks, except that they used to prostitute their daughters, who had no other fortune except what they earned in this way. They punished idleness as a crime, and injured their children from their infancy to hardships. Their arms were not bows and arrows, but long spears anciently used by the cavalry; and if we may believe Herodotus, the Lydians far excelled all other nations in horsemanship. They were the first that introduced the art of coining gold and silver, for facilitating trade; the first that sold by retail, that kept eating-houses and taverns, and that invented public sports and shows, which were therefore called *ludi* by the Romans, who borrowed them of the Tuscans, the descendants of the Lydians. To these diversions they resorted for relief at a time, during the reign of Atys, when a great scarcity of provisions prevailed through the whole kingdom of Lydia. Having contrived various kinds of diversions, as Herodotus informs us, they used to play one

whole day without intermission, eating and drinking the next day without other amusement. After they had continued thus alternately fasting and feasting, and finding that their calamities increased rather than abated, the king divided the whole nation into two bodies, commanding them to determine by lot, which of the two should remain at home, and which should go abroad in quest of new habitations, since their native country could not afford them sufficient maintenance. Those who by lot were constrained to abandon their country, after many adventures, arrived in that part of Italy, which was then called Umbria, and is now named Tuscany. Thus they changed their name, being no longer called Lydians, but Tyrrhenians, from their leader Tyrrhenus.

Although the trade of the Lydians is no where particularly mentioned, we may well imagine that it was considerable, especially under their latter kings, when Lydia was in the meridian of its glory; on account of the splendour of this monarchy and the advantageous situation of the country. The same inference is justified by adverting to the immense riches, not only of the Lydian princes, but of several private persons. Herodotus (lib. vii. c. 23.) mentions one, named Pythius, who not only entertained Xerxes and his whole army, while he was marching with innumerable forces to invade Greece, but made him an offer of 2000 talents of silver, and 3,993,000 pieces of gold, bearing the stamp of Darius. This same Pythius was reckoned the richest man in the then known world. The last king of Lydia was Cræsus (see his article), with whose capture by Cyrus at the siege of Sardis (B.C. 548.) the ancient kingdom of Lydia terminated; and from this time it continued subject to the Persians, till they also were conquered by the Macedonians. Anc. Un. Hist. vol. iv.

LYDIAN, the name of one of the modes in Greek music, which occupied the middle place between the Æolian and Hypodorian. It was also sometimes called the Barbarian mode, from its being invented by a people of Asia. See MODE.

Euclid distinguishes two Lydian modes; that of which we have been speaking, and another called a low Lydian, and which is the same as the Æolian mode, at least as to its fundamental. The character of the Lydian mode was animated and interesting, yet melancholy, pathetic, and proper for voluptuous occasions; on which account Plato banished it his republic. It was said that by this mode Orpheus tamed wild beasts, and that Amphion built the walls of Thebes. Some say that it was invented by Amphion, the son of Jupiter and Anthiope; others by Olympus the musician, and disciple of Marsyas; while there are still others who assign it to Melampides. Pindar says, that it was first used at the nuptials of Niobe.

LYDIAN Games, was a name given to the exercises and amusements invented by the Lydians: they are said to have invented the quoit and games of chance, played with dice. These Asiatics, after they had lost their city, emigrated into Etruria, whither they carried their ceremonies and games. Some Romans, having a passion for foreign play, adopted the Lydian method of gaming, which in the time of the emperors was pursued with such excess, that Juvenal is very severe on the great number of those who were hastening to ruin by that means.

The Lydian games were at first called *Lydi* by the Romans, but afterwards, by corruption, *Ludi*.

LYDIAN Lyre, in the *Ancient Music*. The Trigon instrument or harp of the Asiatics or Barbarians was usually so called.

Julius Pollux, c. 10 of l. iv. Onomast. speaks of a Lydian harmony, mode or tune, proper for the flute, of which he

he ascribed the invention to Anthippus; and a little further, he says, that the Lydian nome proper for the flute was invented by Olympus or Marlyas.

For the scale and names or characters of the notes in the Lydian mode, see *MUSIC of the Greeks*, and *NOTATION*. The Lydian mode corresponded with our key of E.

LYDIAN STONE; *Lydischer stein*, Wern.; *Basanie*, Kirw.; *Pierre coralline* of some French mineralogists; vulgarly *Touchstone*, *Black jaffer*, &c.

Its colour is commonly greyish-black, which sometimes approaches to blueish and velvet black.

It is found massive and in irregular blunt-edged rolled pieces, sometimes traversed by veins of quartz, which are however more frequently seen in the common flint-slate, of which the Lydian stone is considered to be a subspecies.

Externally smooth and glistening; internally it is more or less glimmering. Its fracture is even, approaching to flat conchoidal, and also sometimes to uneven and splintery; in the large it passes into flaty. Fragments indeterminately angular, mostly sharp-edged; they are opaque, seldom translucent at the edges.

It is hard, but less so than quartz; brittle; not very easily frangible. Specific gravity 2.596, Kirwan; 2.880, Grofs; 2.887, Gerhard.

The Lydian stone is, like the common flint-slate, infusible *per se*; and it generally retains its black colour in a very intense heat.

With regard to its geognostic situation it differs considerably from the common *Flint-slate* (which see); for it does not, like this, form entire mountains, but only single strata. Thus it occurs alternating in uniform strata with primitive clay slate, in Saxony, Bayreuth, &c. To Mohs, however, it appears to be only the newer clay-slate formation which contains such strata; since the older clay slate of the lofty ridges of mountains in the Saxon Erzgebirge appears to be entirely destitute of Lydian stone. In secondary formations, such as the greywacke mountains, it occurs partly as rolled pieces (being the products of a destroyed older formation), partly in beds in uniform strata alternating with greywacke and greywacke slate; of this latter numerous examples occur in the Hartz mountains. Of the older formation of this rock, it is worth remarking that it occurs with traces of carbone.

The beds of Lydian stone, where they bask out, appear very much rent, and divided into cubic masses; and, indeed, this cubic form is still more or less discernible in the boulders and rolled pieces of this substance found in brooks and rivers. Mohs.

LYDIAT, THOMAS, in *Biography*, an English mathematician, was born at Okerton, in Oxfordshire, in 1572, and was educated at Winchester-school, from whence he removed to New college, Oxford, where he obtained a fellowship. He applied himself with great assiduity to the study of the languages, philosophy, astronomy, the mathematics, &c. In the year 1603 he resigned his fellowship, and contented himself with living on his patrimonial estate. The next seven years he spent in publishing several books which he had begun in the college, particularly his "Emendatio Teopseurum ab initio mundi huc usque compendio facta, contra Scaligerum." This work was dedicated to Henry, prince of Wales, who appointed him his chronographer and cosmographer. In 1609 he became acquainted with archbishop Usher, who gave him a situation in the college at Dublin, which he held about two years. In 1612 he was presented to the rectory of Okerton. He was a great supporter for his loyalty in the civil wars: at one time he was so completely stripped of all his property, that for three months together he was

under the necessity of borrowing a shirt, to be able to change his linen. He was twice forced away from his own house, and once made a prisoner in Warwick castle. He died extremely poor in 1646, when he was about 74 years of age. In 1660 a stone, with an inscription, was placed over his grave, at the expense of the fellows and wardens of his college: an honorary monument was likewise erected to his memory. He was a person of small stature, but of great parts, and of a public soul: he was a man of considerable and various erudition, and held in high estimation by learned men both at home and abroad. He wrote a great number of books, besides that already referred to, as 1. "De regni annorum formis," and a defence of the same in reply to Clavius and Scaliger. 2. "On the Origin of Fontaines." 3. Several treatises on Philosophy and Astronomy, &c. He left behind him a number of MSS.

LYDOWIARY, in *Geography*, a town of Samogitia; eight miles N.W. of Rostow.

LYE, in *Agriculture*, any watery fluid much impregnated with saline matter. In husbandry the term is generally applied to such fluids as are employed for the purpose of steeping grain; in which cases the best criterion of their strength is that of the swimming of an egg. See *STEEP*.

LYE, EDWARD, in *Biography*, a learned antiquarian, and great master of the Gothic and Saxon tongues, to whose labours we have had frequent occasion to refer, was born at Totness, in Devonshire, about the year 1694, where his father kept a school. He was educated at home till he was about nineteen years of age, when he was admitted at Hertford college, Oxford: here he took his degrees, and in 1719 was ordained priest, and presented to the living of Haughton-parva, in Northamptonshire. In this situation he employed himself in the profound study of the Anglo-Saxon language. His first publication was an edition of the "Etymologicum Anglicanum" of Francis Junius, from the author's MS. in the Bodleian library. To this he prefixed an Anglo-Saxon grammar. In 1750 he was presented to the vicarage of Yardley-Hallings. After this he published the Gothic gospels, with a Gothic grammar prefixed to them: but the great labour of the latter part of his life was his Anglo-Saxon and Gothic dictionary, which he had just finished and put to press, when death terminated his labours in 1767. It was published under the direction of the Rev. G. Manning in 1772.

LYEMMER. See *LYVIER*.

LYGDINUM MARMOR. See *MARBLE*.

LYGDUS LAPIS, in *Natural History*, a name given by some of the ancients to the species of alabaster, which others of them called *marmor lydiacum*, by which name there is only one species.

LYGE, in *Geography*, a town of Norway, near a lake of the same name; 16 miles N.W. of Christianland.

LYGFUM, in *Botany*, one of Loefling's genera, and so called from *lyge*, a seed or fruit, in allusion to the tough planty pulpy nature of the plant. Lodd. Bot. 284. t. 1. Linn. Gen. 31. Schreb. 25. Willd. Sp. Pl. 4. 110. Murr. M.J. Dec. 1. 3. J. Hort. Kew. 4. 1. 120. 121. Juss. 23. Lamarck Illust. t. 2. Richard in Sm. and Ken. Ann. of Bot. v. 2. 543. t. 15. Clavard. order. *Thellandria*. *Lygdium*. Nov. Ord. *Gracilaria*.

Gen. Char. Conch. of one ovate, a isolated, pointed, permanent valve, at length indented, separating at the lower side, and containing two equal, opposite, parallel, and lobate. Cor. of two valves, very hairy at the base, permanent; the outermost ovate, pointed, convex, and 1 1/2 times as long, linear, narrow, acute, cloven at the summit, awnlets. Sperm. Filaments (in each lobe) three, equal, 1 1/2

than the corolla, flattish, very narrow, anthers vertical, linear, cloven at each end. *Pist.* Germen superior, oblong, convex at the outside, flat at the inner; style simple, compressed, the length of the stamens; stigma simple, taper-pointed, incurved. *Pist.* none, except the hardened hairy base of the corolla of each st. rect, united longitudinally to the other. *Seeds* solitary, linear-oblong, convex at the outside, flattish, with a longitudinal furrow, at the inside.

Eff. Ch. Glume of one valve, convoluted, two-flowered. Corolla of two valve, the innermost twice as long as the outer, awnless. Seed solitary, enclosed in the hardened combined base of each floret.

1. *L. Spartum* Badard Mat-weed. Linn. Sp. Pl. 78. (*Sparta herba alterum*; Clus. Hist. v. 2. 220. *Spartum alterum* Phil.; Ger. em. 41.)—The only known species observed by Loesling to be very abundant in the south of Spain, always growing in low places, on a clay soil, where the water stands after much rain. The Spaniards call it *Abaradin*, or *Albaradin*, a name probably retained from the Moors. The root is creeping and perennial. Stems about a span high, erect, rushy, round, slender, smooth, nearly naked, with one joint, above which they are much extended after flowering. Leaves several, sheathing the lower part of the stem, and about equal to it in height, narrow, convoluted, taper-pointed, rushy, smooth; the upper or floral one shorter, with a longer sheath. *Stipula* thin, membranous, oblong, cloven, decurrent. Flower large, terminal, solitary, at first erect, inclining as the seeds ripen, with a knot at the base. Calyx smooth, delicately striped with green, at length opening and exposing the long dense hairs which clothe the base of the permanent corolla, investing the seed.

The error of Linnæus and Loesling, who supposed the germen to be inferior, and common to two florets, is properly corrected by Richard, who shews the supposed two-celled nut to be formed merely of the hardened combined bases of the corollas of the two florets. This is analogous to many other true grasses, (as this is,) whose hardened corolla becomes a husk or shell to the seed. In other points the description of Richard is scarcely, if at all, superior to that of Loesling.

This plant, being far inferior in tenacity, as well as length, to the true *Spartum* or Mat-weed, *Stipa tenacissima* of Linnæus, serves chiefly in Spain for stuffing mattresses. It flowers in May and June, ripening seed in autumn, and often retaining its empty sheath or calyx till the following summer. The parts of fructification are, on the whole, perhaps larger than those of any other grass.

LYGINIA, from *λεγις*, twiggy, alluding to its hard tough rushy habit. Brown Prodr. Nov. Holl. v. 1. 248. (*Schoenodum*; Labillard. Nov. Holl. v. 2. 79.)—Class and order, *Dincoia Monadelphica*. Nat. Ord. *Tripetaloideæ*, Linn. Jumi. Juss. *Rhizaceæ*, Brown.

Eff. Ch. Male, Spatha of one valve. Petals six. Filaments united lengthwise. Anthers three, didymous, cloven at each end.

Female, Spatha of one valve. Petals six. Style in three deep divisions. Capsule three-lobed, three-celled, bursting at the prominent angles. Seeds solitary.

The root is scaly, creeping, with thick downy fibres. Stems simple, round, leafless, with several sheathing scales, easily breaking at the joints. Spike terminal, of several crowded tufts of flowers, each accompanied by a common sheathing bractea, the female flowers sometimes solitary.

1. *L. imberbis*. Bracteas and spathas beardless. Male and female tufts many-flowered.—Native of the south part of New Holland.—This is *Schoenodum tenax*, the male plant, of Labillardiere, t. 229. f. 1. Mr. Brown observes, that

this supposed species of the French author is made up of two different genera; he therefore thinks it safer to reject the generic name entirely, than to retain it for either the male or female plant, which might lead to error. To this determination we gladly assent, especially as the said name, being composed of another established one, *Schoenus*, is absolutely inadmissible, and its termination being altered for the worse from *Schoenoides*, (which the author gives as his meaning) not in any manner removing the objection.

2. *L. barbata*. Bracteas and spathas bearded. Male tufts of few flowers; female ones single-flowered, nearly solitary. From the same country. These plants have much of the habit of *Reflexa*, *Elegia*, &c. See LEPYRODIA.

LYGISMOS, from *λεγειν*, to distort, in Surgery, a distortion of the limbs; sometimes a luxation.

LYGMOS. See HICKUP.

LYGODIUM, in Botany, from *λεγειν*, pliant, tough, and *στένδρ*, expressive of the habit of this elegant genus, which consists of ferns with twining stems. Swartz Syn. Fil. 152. Sim's and König's Annals, v. 2. 305. t. 10. f. 2. Sprengel Crypt. 176. t. 5. f. 39. Brown Prodr. Nov. Holl. v. 1. 162. Bernhardi in Schrad. New Journ. v. 1. fasc. 2. 39 t. 3. (Ugena; Cavan. Leccion. 551. Hydroglossum; Willd. Abhandl. 20. t. 1. 2. Odontopteris; Bernhardi in Schrad. Journ. for 1800. 127. t. 2. f. 4. Gifopteris; ibid 129. t. 2. f. 1. Ramondia; Mirbel Bull. des Sciences an 9. 179.)—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*, Linn. Juss. *Filices Osmundaceæ*, Brown.

Gen. Ch. Capsules without a ring, ovate, reticulated with veins, pellucid, radiated with furrows at the top, bursting lengthwise, sessile, reversed, attached by their middle, in two rows, on narrow processes of the frond at its back, forming little, simple or forked, spikes. *Involucrum* consisting of separate scales, alternate with the capsules, originating from the veins of the frond, unconnected at their upper part.

Eff. Ch. Capsules sessile, ovate, attached by their middle, reversed, radiated at the top, in two rows on the back of narrow processes of the frond. *Involucrum* of solitary scales, separating the capsules.

Obs. Mr. Brown has first remarked the great peculiarity of the insertion of the capsules, they being attached by their middle, not by their base. The stem is long, twining, and climbing. Leaves in pairs, on one common cloven footstalk, each of them either divided or compound. Fructification either fringing their lobes in the form of minute, pale, chain-like spikes, or rarely composing the whole of certain leaves, transformed as it were into a compound forked assemblage of spikes. See Willd. t. 1. f. 2.

Swartz defines eleven species, to which Mr. Brown adds a twelfth, found in the tropical region of New Holland, which he calls *L. finikippinnatum*.

Beautiful specimens are

L. scandens. Sw. n. 1. (*Ophioglossum scandens*; Linn. Sp. Pl. 1518. *Ugena feminafastata*; Cav. Ic. v. 6. 74. t. 594. f. 1. *Adiantum volubile minus*; Rumph. Amb. v. 6. 75. t. 32. f. 2, 3. *Filix*; Petiv. Gazoph. t. 64. f. 11.)—Stem round. Fronds pinnate. Leaflets stalked, oblong; heart-shaped or lobed at the base: the barren ones finely serrated.—Native of the East Indies, and of Brazil. This rises to the height of several feet.—The fronds or branches spring in pairs from a woolly-topped knob, and are each a span long, of about eight or ten alternate, stalked, oblong leaflets, with an odd terminal one of larger size. Each is fringed with numerous short, rather hairy, spikes.

L. circinnatum. Sw. n. 6. (*Ophioglossum circinnatum*; Burm.

Burm. Ind. 228. *O. flexuosum*; Linn. Suppl. 443, not Sp. Pl. 1:10. *Adiantum volubile polypoides*, five majus; Rumph. Amb. v. 6. 75. t. 33.)—Stem round. Fronds palmate, in three or four lance late entire taper-pointed lobes; the fertile ones much contracted.—Native of the East Indies. We have it from Tranquebar.—The leaves are deeply palmate, smooth, entire, pale green. Spikes marginal, very short, almost round.

Linnaeus confounded this with the *Palli-panna*, Hort. Malab. v. 12. 63. t. 32, which seems to be his real *O. flexuosum*, and is *Lygodium flexuosum* of Swartz, n. 5.

LYGON and LYGUS, are used for *agnus callus*.

LYGUM, in *Geography*, a town of Denmark, in the duchy of Sleswick; 14 miles W. of Apenrade.

LYING-IN HOSPITAL. See HOSPITAL.

LYING-IN Women, Disorders of. See LABOUR, LOCHIA, FEVER, AFTER-PAINS, &c.

LYING-IN Women, Treatment of. See LABOUR.

LYING under the Sea, in *Sea Language*, is when, in a storm, the ship is a-hull, and the helm so fastened a lee, that the sea breaks upon her bow, or broadside.

LYING along, denotes the state of a ship, when pressed down sideways by a weight of sail in a fresh wind that crosses the ship's course either directly or obliquely.

LYING-to, or *Lying-by*, denotes the situation of a ship when she is retarded in her course, by arranging the sails in such a manner, as to counteract each other with nearly an equal effort, and render the ship almost immoveable, with respect to her progressive motion or head-way.

A ship is usually *brought-to* by the main or fore-top-sails, one of which is laid a-back, whilst the other is full; so that the latter pushes the ship forward, whilst the former resists the impulse, by forcing her a-tern. This is particularly practised in a general engagement, when the hostile fleets are drawn up in two lines of battle opposite to each other: it is also used to wait for some other ship, either approaching or expected; or to avoid pursuing a dangerous course, especially in dark or foggy weather, &c. Falconer.

LYING-to in a Storm. See TRYING

LYKSBORG, or LUXBURG, in *Geography*, a town of Denmark, in the duchy of Sleswick, on a promontory near the Baltic; 7 miles N.E. of Flensborg.

LYKSALE, a town of Sweden, in the Lapmark of Umea; 80 miles S.S.W. of Umea

LYMAN, a township of America, in Grafton county, New Hampshire, situated at the foot of a mountain on the east side of Connecticut river, between Littleton and Bath, 7 miles W. by N. of New Concord; incorporated in 1761, and containing 533 inhabitants.—Also, a town in the county of New York, Maine, north of Wells and east of Alfred, to each of which it adjoins.

LYME, a town of Grafton county, New Hampshire.—Also, a port-town in New London county, Connecticut, the "Nehamick" of the Indians, at the mouth of the Connecticut river, on its east side; settled about the year 1664, and incorporated in 1667; and containing, in three parishes, 4380 inhabitants.

LYME REGIS, a sea-port, borough, and market-town, in the hundred of Whitchurch, in Bridport division of Dorsetshire, England, is situated 23 miles distant from Dorchester, and 143 from London, on the little river Lyme, near the sea. Its situation, in a cavity between two rocky hills, on a declivity, makes it difficult of access; and that part of the town nearest to the sea is so very low, that at spring-tides the under-rooms and cellars are overflowed to the depth of ten or twelve feet. Lyme is mentioned in history in the eighth century, when Cenwulf, king of the West

Saxons, granted, in a charter to the church of Sherborne, "the land of a mansion near the west back of the Lim, so that salt for the said church should be boiled there." In the Domesday Survey we find the manor of Lyme as being in three divisions or parcels. Edward I. granted Lyme the liberties of an haven and borough; and from that period it increased in buildings, and became so prosperous, that it was able to furnish Edward III. with four ships, and fifty-two mariners, for the siege of Calais. In the reigns of Henry IV. and V., the southern coast of England was much annoyed by the incursions of the French: this town severely experienced their effects; and being also afflicted by other calamities, its trade declined considerably. It has since been occasionally retrieved and reduced; but is now recovering its importance through the residence of merchants, who have recently erected some handsome stone-houses; and as the harbour is considered one of the best in England, the town is capable of great improvement. During the civil war in the reign of Charles I., Lyme was a place of great consequence to the contending parties, especially to the royalists; great part of their dependence on the west of England arising from being in possession of this town. The siege of Lyme was one of the most remarkable that occurred during that eventful period. In the reign of James II., Lyme was distinguished by the landing of the duke of Monmouth here on his unfortunate contention for the kingdom, and by the sanguinary executions which took place on his defeat.

The privileges granted by Edward I. to this town have been confirmed and increased by several succeeding sovereigns. The corporation consists of a mayor, who acts as a justice in the years before and after his mayoralty, a recorder, town-clerk, and fifteen capital burgesses, of whom two with the mayor are justices. The royalty of the manor is vested in the corporation. Lyme has been represented in parliament ever since the twenty-third year of Edward I. The right of election is in the mayor, burgesses, and freemen; the voters being between thirty and forty. The church is a neat, though ancient edifice, but is not particularly worthy of notice. The custom-house is a modern brick building, supported on pillars, for the convenience of the corn-market, which is held beneath. The quay is commodious, though not spacious; and round the harbour are several small forts mounted with cannon for its defence. The principal public work, however, is the cobb, or pier, which, in its ancient state, was composed of vast pieces of rocks rudely piled on each other; but is now formed of stone. This is a fabric of the greatest utility on this coast, there being no other shelter for shipping between the Start point and the Portland road; and although at this place the south-west wind blows with extreme violence, vessels ride in the harbour in perfect security. The cobb has suffered very much by these winds: it was totally destroyed in the reign of Richard II.; and in the last century it sustained great injury by three storms, but was repaired by government at the expence of 6000*l*. Charles II. granted 100*l*. per annum towards its repair, out of the customs of the port, which is still continued; and the inhabitants annually choose two cobb wardens to superintend the improvement. The population of this town, in the year 1801, was stated to be 1451; the number of houses, which are chiefly constructed of blue rag-stone, and covered with slate, was 276. A market is held on Saturdays, and two fairs annually.

Lyme was the birth-place of Thomas Coram, the benevolent patron and contriver of the Foundling hospital in London. He died March 19, 1751, in his eighty-fourth year, and was buried in the vault under the chapel of the hospital.

hospital, where an inscription perpetuates his memory. *Beauties of England and Wales*, vol. iv. Hutchins' *History and Antiquities of Dorsetshire*, 2 vols. folio.

LYMFORD, or LYMFURT, a gulf of Denmark, near the west coast of North Jutland, communicating with the Cattegat, and running 80 miles inland, gradually widening, and separated from the North sea only by a narrow strip of land. *N. lat.* 56° 29'.

LYMINGTON, a borough and market-town in the parish of Boldre, in the New Forest of Hampshire, England, is situated on the declivity of a rising ground, on the eastern bank of the Lymington river, about a mile from its confluence with the sea; at the distance of 16 miles from Southampton, and 95 from London. It is of remote, though unknown origin: from a consideration of local circumstances, Mr. Warner supposes that a town or village was formed near this spot by the Britons. That the Romans were acquainted with it, is evinced by the contiguity of an encampment called Backfield Rings, or Cattle Field, and by the evidence of Roman coins, nearly 200 lbs. weight of which, of the Lower Empire, were discovered here in two urns in the year 1741. Lymington occurs in Domesday Book under the name of Lymtint; but it does not seem to have attained any considerable importance till it became the property of Baron de Redvers, in the time of Henry I.; when, a port being established, the wines of France, and other foreign commodities, were unshipped at its quays. It then also became famous for its salt-works; though this manufacture is, with great probability, supposed to have been established at a much earlier period. A very extensive manufacture of marine salt is now carried on here: the works are situated on the borders of the sea-shore, and reach nearly three miles in a south-west direction. The town consists principally of one long street, and is divided into the *new* and *old* town by the church, which, though originally a regular pile, consisting of a nave, chancel, and aisles, with a spire in the centre, is now, through successive alterations, become extremely informal. The town hall is a neat building: and here are two sets of baths, which are rendered very convenient, and are much frequented. Lymington was summoned as a borough to send representatives to parliament in the reign of Edward III.; but it does not appear to have complied with this precept till the 27th of Elizabeth. In the reign of James I. it was incorporated by charter, and from that period the returns have been regular. The right of election is vested in the mayor and burgesses, in number about eighty. The population was stated, under the act of the year 1800, to be 2378; the houses 402. A market is held on Saturdays; and two fairs annually. The situation of Lymington, on the banks of a navigable river, and so contiguous to the sea, is extremely favourable for trade; but this advantage was formerly much greater than at present, as, by the injudicious contraction of a causeway, the depth of the river has been considerably lessened, and its channel contracted. Previous to the making of this causeway, which was about the year 1730, vessels of upwards of 500 tons burthen could be brought up to the quay; though now one of 300 tons can scarcely be navigated. *Beauties of England and Wales*, vol. vi. Warner's *Account of Lymington*, 12mo.

LYMPHA, LYMPE, in *Anatomy*, a term given to the transparent fluid conveyed in the absorbing vessels of the body; also to a part of the blood. (See *ABSORPTION* and *BLOOD*.) It is often applied also to other animal fluids, chiefly when clear and nearly transparent.

LYMPHÆ DUCTUS, a name given sometimes to the lymphatic vessels.

LYMPHE, among the *Romans*, a kind of grottoes, or artificial caves, so called from *lymphæa*, water; because they were furnished with a great many tubes, canals, and secret passages, through which the water suddenly gushed upon the spectators, while busy in admiring the great variety and beautiful arrangement of shells, with which the grotto was adorned.

LYMPHATI, or LYMPHATICI, in *Antiquity*, a name given by the Latins to possessed or mad persons, because they were thought to be gifted with divination. *Plin. Nat. Hist. lib. xxv. cap. 5. p. 368. edit. Hard.* See *LARVATI*.

These answer to the *αμφοτερις* of the Greeks: the ancient Greeks called water *nymphæa*, which the Latins changed into *lymphæa*. The term *emphæ*, says Mr. Bryant, is of great antiquity, and denotes an oracular influence, by which people obtained an insight into the secrets of futurity: it was written *emphi* or *emphi*, and signified the oracle of Ham, who, according to the Egyptian theology, was the same as the sun, or Osiris: and as fountains were deemed sacred, they were styled by the Ammonians *Ain emphæ*, or the fountains of the oracle, from the divine influence with which they were supposed to abound, which terms were afterwards contracted by the Greeks into *emphæ*, a nymph, who supplied such a person to be an inferior goddess who presided over waters. In the same manner from *al emphæ* was derived *lymphæa*, which differed from aqua or common water, because it was of a sacred or prophetic nature. *Analysis of Ant. Myth. vol. i. p. 280.*

LYMPHATICS, in *Anatomy*, are the absorbing vessels. This system is an assemblage of numerous small vessels, arising from all parts of the body, carrying from them various fluids, which they pour into the venous system, after making them pass through certain small bodies called lymphatic glands, and forming part of the same system with them. The term lymphatics was applied to these tubes in consequence of their containing, in general, a transparent fluid or lymph; and it designates, therefore, properly speaking, only those absorbents, of which the contents resemble lymph. The vessels, which take up the chyle from the intestines, are called lacteals, from the appearance of their contents. As the structure and offices of the organs are the same in all parts, these distinctions might lead to erroneous views of the subject; and the term absorbents, which denotes their general function, seems the most appropriate. Names derived from the nature of the fluid absorbed are more particularly objectionable, because that is very imperfectly known to us. We cannot suppose that one and the same fluid is absorbed from ferous cavities, from the adipous cells, from muscles, glands, bones, &c.; yet in all these cases it goes under the common and very indefinite term lymph.

Like the termination of the exhalants, the origin of the absorbents cannot be demonstrated. They are so extremely delicate, that the eye, assisted even by the best optical instruments, cannot discern them: we must therefore infer their existence from phenomena, and conclude that absorbing vessels arise wherever absorption takes place. An attentive examination of absorptions shews us that they occur wherever there is exhalation; so that the same table may serve both for exhalants and absorbents. The following one represents the latter.

Absorbing vessels.	1. External, arising on	<ul style="list-style-type: none"> 1. The mucous surfaces. 2. The skin.
	2. Internal, arising on	<ul style="list-style-type: none"> 1. The serous surfaces. 2. The cellular system; and deriving from it <ul style="list-style-type: none"> 1. Serum. 2. Fat. 3. The medullary system <ul style="list-style-type: none"> 1. Of short and broad bones; and the extremities of long bones. 2. Of the middle of long bones. 4. The synovial system <ul style="list-style-type: none"> 1. Of the joints. 2. Of tendinous sheaths.
	3. Of nutrition, taking up the residual nutritive matter of each organ.	

The structure, properties, functions, and distribution of the absorbing systems, both the vessels and glands, are considered in detail in the articles **ABSORBENTS** and **ABSORPTION**.

LYMPHATICS of Birds and Fishes. See *Anatomy of BIRDS* and *FISHES*.

LYNCHBURG, in *Geography*, a post-town of Virginia, in Bedford county, on the S. side of James river, nearly opposite to Maddison, and one mile distant. It contains about 100 houses, and a large warehouse for the inspection of tobacco; 12 miles from London.

LYNCHET, among *Farmers*, a line of green sward, serving as a boundary to separate ploughed land, in common fields. See **BALKS**.

LYNCHVILLE, in *Geography*, a post-town of Marion county, South Carolina, 450 miles from Washington.

LYNCIS LAPIS, in *Natural History*, the name given by some of the writers of the middle age to the *lelemites*.

LYNCURIUM, or **LYNCURIVS**, in *Mineralogical Antiquities*, a mineral substance, respecting the nature of which several conjectures have been broached, from the time of Pliny down to the present day. The opinions of the present mineralogists appear to be divided between amber and hyacinth; but it is most probable that both these substances have been confounded under the name of lyncurium. Pliny, in speaking of the mineral in question, is inclined to deny its very existence: "De lyncuris," he says "maxime dici cogit auctorum pertinacia. Quippe etiam electrum id esset, lyncurium tamen gemmam esse contendunt. Fieri autem ex urina quidem lyncis, sed congelata terra proximus bellia aperiente eam, quoniam invidet hominum usui. Esse autem qualem in igneis succinis, colorem, scalpique. Nec folia tantum aut stramenta ad se rapere, sed etiam ac ferri laminas, quod Dioecles quidem et Theophrastus credidit. *Zepo falsum id totum arbitror, nec visum in reo nostro gemmam ullam ea appellatione.*" (Hist. Nat. xxxvii. 3.) It is remarkable that Pliny, whose incredulity upon other occasions was certainly not over great, should have treated the whole of what has been said of the lyncurium as a mere fable, when his scepticism might have more properly been confined to that part of the story which relates to the origin of the substance in question. Instead of this, in speaking of the lynx, he actually gives credit to what has been said of the extraordinary quality of its urine. "Lyncium humor (he says) ita red litus ubi gignatur glaciatur, arefactive in gemmas, carbunculis similes, et igneo colore fulgentes, lyncu-

rium vacatas, atque ob id succino a plerisque ita generari prodito." Ib. viii. 38.

Theophrastus, from whom Pliny has principally derived his information respecting lyncurium, mentions among its qualities that of attracting, like amber, particles of straw, and even thin laminae of copper or iron. Our hyacinth does not possess the quality of becoming electric by friction; a circumstance to which Sir John Hill does not advert in his observations on this stone, which he considers as the only one that can be said to answer the description given of the lyncurium by Theophrastus. On the other hand, it must be confessed that its remaining qualities, as mentioned by the Eresian philosopher, *viz.* the considerable hardness attributed to it, and the consequent use made of it for engraving seals on, do not exactly square with the well known characters of amber, which is moreover separately described in his work as a substance perfectly distinct from lyncurium.

It is more than probable, that in this case, as in many others, the qualities of two distinct substances have been erroneously combined by the ancients, who, in their attempt to identify natural bodies, were but too often strangely misled by a fancied similarity of characters, where the eye of a modern naturalist would scarcely discover traces of the most distant resemblance.

It would appear that the finest amber, and a particular deep-coloured variety of it, was formerly obtained from Liguria, where, indeed, it still occurs, though not in the same quantity in which it is found on the sea-coast of Prussia. If we may suppose the word *lyncurium* to have been derived from that part of Italy, it is certainly equally probable that ignorance and the love of the marvellous may afterwards have substituted that of *lyncurium*, implying the fabulous origin of this substance from the urine of the lynx. Similarity of colour appears to have been sufficient afterwards to affix the same appellation to the hyacinth; and it is probably this confusion which produced the description of Theophrastus above alluded to, and which is partly applicable to amber, and partly to the hyacinth, or any other hard stone of similar colour and transparency, such as yellow garnets, yellow calcedony, &c.

Among the authors who have considered amber to be the lyncurium of the ancients, are Geoffroy, G. Ser. Bel. Lion, and Napione; most of the other modern writers on mineralogy follow St. Epiphanius, Lefler, and Hill, who are decidedly of opinion that the hyacinth alone could have been meant by it. Sir William Watson supposes that Theophrastus

tus's description is applicable to the tourmalin, the electrical phenomena of which are however of a peculiar nature; not to mention other objections that may be urged against the identity of the two substances.

Of other opinions on this subject none deserve to be mentioned, except, perhaps, on account of its singularity, that of Woodward, and some writers before and after him, who supposed the lyncurium to be the calcareous petrification known by the name of *belemnites*. Indeed it is difficult to guess what can have given origin to this strange supposition, unless it be the circumstance that these belemnites, when burnt, are said to give out an unpleasant urinous odour.

In the Vulgate, mention is made of the ligurius, as one of the twelve precious stones in the breast plate of the high priest. In the version of the Septuagint, it is called *Λυγυρίων*. St Epiphanius, enumerating the same twelve gems, gives the following account of the stone in question: "Ligurius vel lyncurius gemma; de hujus inventione vel apud naturæ indagatores, vel apud alios veteres qui harum rerum meminerunt, nihil cognovimus. Invenimus tamen languriam gemmam vocatam, quam vulgari lingua ligurium appellant. Et forte puto hunc esse lygurium." (St Epiph. Opp. latine.) The same writer and Hieronymus suspect the lyncurium to be the hyacinth; but how unsettled the ideas of St. Epiphanius were respecting the latter gem, appears from the following account he gives of it: "Hyacinthus igitur diversas habet formas; quo enim reperitur colore profundior, eo cæteris præstantior est. Similis est lane quæ subpurpurascit aliquatenus." (i.e. pag. 110.)

LYNDEBOROUGH, in *Geography*, a township of America, in Hillsborough county, New Hampshire, about 70 miles from Portsmouth; incorporated in 1764, and containing 676 inhabitants.

LYNDHURST, a village in the parish of Minsted, in the New Forest of Hampshire, England, is situated nine miles from Southampton and 16 from London, nearly in the centre of the New Forest, of which it has been, from the formation of the forest, considered as a sort of capital; and here was exercised the jurisdiction of the chief justice in eyre for this forest, so long as he continued to exercise it, of which there are no traces subsequent to the reign of Charles II. All the Forest courts under the verderors are still held here; as well as those of attachment, &c. as the swanmote: the former are held on such days as the presiding judges appoint, three times in a year; the latter on the 14th of September annually. The king's house, in this village, though but an indifferent residence, is occupied by the lord warden whenever he visits the Forest. An ancient surrip is preserved here, said to have been worn by William Rufus at the time he was shot by sir Walter Tyrrell. The king's stables are very large, and were probably considered as magnificent when first erected, which appears to have been about the time of Charles II. From the hotel at Lyndhurst, which is entirely new built, and fitted up with every convenience, is a fine view of the sea, and of the Needle rocks at the west end of the Isle of Wight. Under the population act of 1820, Lyndhurst was returned as containing 181 houses, inhabited by 582 persons.

About one mile west of Lyndhurst is Cusnells, the seat of the right honourable George Rose, who has been here honoured with two visits from their majesties and the royal family in the years 1831 and 1834. Beauties of England and Wales, vol. vi. Gilpin's Observations on the New Forest, &c. 2 vol. 8vo.

LYNDON, a township in Caledonia county, Vermont,

N. of St. Johnsbury, and S. of Burke and Billymead; containing 622 inhabitants.

LYNN, *Sæcis* of the Indians, a maritime post-town of America, in Essex county, Massachusetts, on a bay, N.E. of Boston bay, and about nine miles N. by E. from the town of Boston. The township was incorporated in 1637, and contains 2837 inhabitants. In this township are two parishes, besides a society of Methodists, and a large number of Friends. The principal manufacture is that of women's silk and cloth shoes, which are sold for home use, and shipped to the southern states and to the West Indies. Lynn beach, which is a mile in length, connects the peninsula, called "Nahant" with the main land. In the summer season it is a place of great resort from neighbouring towns, and used as a race-ground.

LYNN River, a river of Norfolk county, in Upper Canada, which rises in Windham township, and discharges itself into lake Erie, affording a good harbour for batteaux.

LYNN Canal, an inlet on the W. coast of North America, and upper arm of Cross sound; extending about 60 miles N. from the N. extremity of Chatham Sound; so named by Capt. Vancouver, from Lynn, the place of his nativity. The entrance to the S. is in N. lat. 58° 12'. E. long. 225° 12'.

LYNNFIELD, a township of America, in Essex county, Massachusetts, N.E. of Salem, and 15 miles N. by E. from Boston; incorporated in 1782, and containing 468 inhabitants.

LYNNHAVEN LAKE, a bay at the S. end of Chesapeake bay, into which Lynnhaven river discharges its waters; lying between the mouth of James's river and cape Henry.

LYNN-REGIS, or KING'S LYNN, a large respectable sea-port, borough, and market town, in the hundred of Freebridge Lynn, in the county of Norfolk, England, is situated ten miles from the British ocean, on the eastern bank of the Great Ouse river, which at this place is nearly the breadth of the Thames above London bridge. Lynn is distant from Norwich 44 miles, and from London 96. It is written Lun and Lena in Domesday book; and appears to have been, at the time of that survey, a place of some consequence and trade. Previous to the reign of Henry VIII. it was called Bishop's Lynn, but falling into the possession of that monarch he changed its name to Lynn Regis. The town is nearly one mile and a quarter in length; its greatest breadth being half a mile. Four small rivers, called Fleets, divide it into several parts, which are connected by eleven bridges. The whole is encompassed on the land side by a deep wet foss, flanked by a wall, which was formerly defended by nine bastions, but is now in a dilapidated state. At the north end is a platform battery, called St Anne's port, mounted with ten eighteen pounders, which were planted here in 1627. Great improvements have been recently made in the streets and avenues of the town.

Lynn has had fifteen charters granted to it by various sovereigns of England. It was first incorporated by king John; and has sent two burgesses to parliament ever since the twenty-sixth year of Edward I. The right of election is vested in the freemen and free burgesses, in number about 350. The corporation consists of a mayor, recorder, twelve aldermen, and eighteen common council-men. By the population survey, made in the year 1800, the number of houses was 2012, occupied by 10,096 persons.

The town contains several public buildings, some of which exhibit curious specimens of architectural antiquity. The principal

principal is the church of St. Margaret, which, with a priory, was founded by Herbert, bishop of Norwich, in the time of William Rufus. It was a very spacious structure, and though now curtailed of its original dimension is still a large and noble pile. It consists of a nave with aisles, a chancel or choir with aisles, a transept, and two towers at the west end; the roof is supported by twenty-two columns, which separate the body from the aisles. At the eastern extremity of the town is an ancient edifice, called the Lady's or the Red Mount chapel; which consists of an octagonal wall of red brick, and is constructed on a very singular plan. Within this is a handsome cruciform chapel, seventeen feet in length, fourteen in breadth, and thirteen in height; the roof is formed of stone, with numerous groins, &c. exactly resembling the ceiling of King's college chapel, Cambridge. This curious structure is verging to decay. St. Nicholas's chapel, built about the time of Edward III., is 200 feet in length, 78 in breadth, and 170 feet from the foundation to the top of the tower. The body consists of a nave separated from the aisles by ten slender columns on each side, supporting an equal number of acutely pointed arches; the roof is groined, and the entrance doors are finely carved. A large monument of white marble commemorates sir Benjamin Keene, K.B. a native of this town, and many years ambassador to the court of Madrid, in which city he died, Dec. 15. 1757; his remains were brought here for interment. The east and west windows of this chapel are large, and are both adorned with numerous mullions and tracery. The southern porch is profusely ornamented with tracery, riches, &c. A view and plan of this porch, with plan, views, section, &c. of the Red Mount chapel, also historical and descriptive accounts of the two buildings, are published in Britton's Architectural Antiquities of Great Britain, vol. iii.

The chapel of St. James, after the dissolution, being in a ruinous condition, was rebuilt in 1682, and converted into an hospital for fifty poor people. Great additions have since been made to the building, and it is now the general workhouse for the town. The Exchange, or Custom house, which was erected in 1683 by sir John Turner, knt. is a neat freestone building, with two tiers of pilasters, the lower in the Doric, and the upper in the Ionic order; it occupies the site of an old religious house, which was appropriated to the Trinity guild. Several other religious establishments were founded here, of which few vestiges remain, except an hexagonal steeple, belonging to the monastery of the Grey friars, which serves as a good land-mark to vessels entering the harbour. Two markets are held on Tuesdays and Saturdays, in different places: the Tuesday market-place comprises an area of three acres, surrounded by some good houses; near the centre, on an ascent of four steps, stands a building, called the Market-cross, of freestone, erected in the year 1710; the lower part is encompassed by a peristyle formed by sixteen Ionic columns; the upper part is finished with a cupola, and the whole is seventy feet in height. The Saturday market is kept in a convenient area recently opened near St. Margaret's church-yard. The Guildhall is an ancient structure of stone and flint; it contains a large stone hall, courts for the administration of justice, and three spacious assembly rooms. On the first Monday in every month, the mayor, aldermen, magistrates and clergymen meet, to hear and determine all controversies between the inhabitants, in an amicable manner, for the prevention of law-suits. This laudable practice originated in the year 1558, and is called the Feast of Reconciliation. This town, not having any fresh springs, was formerly much distressed for water; but it is now supplied from a river near Gaywood, whence

the water is conveyed by small canals, to the conduits in the town.

Lynn harbour is deep, but the approach is bad, from the oozy bed of the river. It is capable of receiving three hundred sail of shipping. At present it is considered as a haven, and not an anchorage. It is the principal emporium of Henry III. Lynn attained to considerable importance, gradually rose from its primitive obscurity, and is now daily becoming a considerable port. Its situation, on the north-east coast, and the inland navigation connected with it, gives the town great commercial advantages. It is open to a communication with all the north of Europe; and, by means of the Ouse and its collateral rivers, can extend its navigation into eight counties, exclusive of other conveyances by land carriage and canals. It imports annually about 100,000 chaldrons of coals, and above 200 pipes of wine; in which two articles it exceeds all other ports in England, except London, Bristol, and Newcastle. It returns to the sea, and other heavy articles, with which it supplies the interior, it receives back for exportation corn and various manufactured articles. Beauties of England and Wales, vol. xi. Richard's History, &c. of King's Lynn, Svo. 1811. Parkin's History of Lynn, folio.

LYNX, in *Astronomy*, is a constellation of the northern hemisphere, made by Hevelius out of unformed stars: the number of stars in Hevelius's catalogue is nineteen, and in the Britannic is forty-four. See CONSTELLATION.

LYNX, in *Mythology*, was a fabulous animal consecrated to Bacchus. See FELIS LYNX.

LYNX, in *Zoology*. See FELIS LYNX.

LYNX, *Persian*. See FELIS CARACAL.

LYOE, in *Geography*, a small island of Denmark, near the S. coast of Funen. N. lat. 55° 3'. E. long. 10° 10'.

LYOENA, a town of Africa, in the kingdom of Algiers, where the independent Arabs lodge their riches as in a place of safety; as it is defended by a warlike tribe, who have withstood the power of the Turks; 106 miles S. of Constantina.

LYON, a river of Scotland, which rises in Loch Lyon, on the S.W. part of the county of Perth, and runs into the Tay; 2 miles E.N.E. of Kenmore.

LYONNET, PETER, in *Biography*, an eminent naturalist, was born at Maellricht in 1707. He acquired a good knowledge of modern and ancient languages, understood music, and was a good engraver and sculptor. He had been originally bred to the law, and became secretary to the states of Holland. In the latter years of his life he applied the whole force of his mind to the study of natural history, particularly to the science of entomology, on which he wrote several books. He died at the Hague in 1789: he had been elected a member of the Royal Society of London, and of several foreign academies.

LYONNOIS, in *Geography*, *Pagus Lugdunensis*, was, before the revolution, a province of France, bounded on the N. by Bourgogne and Maconnois, on the E. by the Saône and the Rhone, on the S. by Languedoc, and on the W. by Auvergne; lying between 45° 15' and 46° 15' N. lat. and between 3° 45' and 4° 50' E. long; being 24 leagues from N. to S. and 16 from W. to E. This province is watered by the Rhone, the Saône, and the Loire, and is moderately fertile, producing grain, wine, and fruits. It was annexed to the crown of France in 1563; and consisted of three small provinces, viz. Lyonnais Proper, Forez, and Beaujolais. The former, being thirteen leagues in length, and eight in breadth, is diversified with hills, gentle eminences, and plains. It yields little grain; but some districts furnish good wine, and excellent pasturage. It has a copper mine,

and a mineral spring. Forez consists principally of an extensive and fruitful valley, yielding grain, wine, hemp, and chequins, and is watered by the Loire and other streams. Beaujolais is a fertile district, twelve leagues in length, and seven in breadth. Lyons and Beaujolais are now included in the department of the Rhone and Forez in that of the Loire.

LYONS, in *Geography*, a small island in the East Indian Sea, near the E. coast of Oby. S. lat. $1^{\circ} 35'$. E. long. $128^{\circ} 14'$.

LYONS, *Lugdunum*, a city of France, and capital of the department of the Rhone; but, before the revolution, the capital of the province called Lyonnais, above described, situated at the conflux of the Rhone and the Saone; over the former there are two bridges, and over the latter three. This city was one of the places conquered by Cæsar; but a little after the death of this dictator, Munatius Plancus received orders from the Roman senate to re-assemble at Lugdunum the inhabitants of Vienno, who had been driven from this city by the Allobroges. In a little time this colony became very powerful, so that Strabo says it was not inferior to Narbonne, with respect to number of inhabitants. In the fifth century this city was taken by the Burgundians, whose king became feudatory to Clovis. The sons of Clovis, however, subdued the Burgundians, and took possession of Lyons. When the dominions of Lewis Debonnaire were divided, Lyons, with the greatest part of Burgundy, was transferred to Lothaire. Before the revolution, it was the see of an archbishop, who was primate of France, and was reckoned the second city of the kingdom in trade, manufactures, and commerce; and was supposed to contain 150,000 inhabitants. These were, in all periods, distinguished for industry, arts, and love of freedom. Under the Romans, as a municipium, it possessed valuable immunities; and when it became a colony, it was cherished and protected. Under the sovereigns of France, it has enjoyed peculiar privileges, being governed by its own magistrates, and guarded by its own militia. Four annual fairs, each of fifteen days, instituted in the reign of Lewis XI., have much contributed to the advancement of its traffic. Its good government naturally attracted citizens, whilst the troubles excited at various periods in the neighbouring states, more especially about the year 1200, between the contending factions of the Guelphs and Ghibelines, occasioned many from Italy and Florence to take refuge in a city where they could live in security and peace. The principal dependence of Lyons, and the source of its wealth, have been its manufacture of silk in all its branches. The trade of Lyons has been immense with Spain, Italy, Switzerland, Germany, Holland, England, &c. From Spain, the inhabitants received wool, silks, drugs, pialtres, and ingots of gold and silver, in return for cloth, linen, saffian, coffee, paper, &c. To Italy they sent cloth, linen, silk stuffs, lace, books, mercury, and salinery, receiving in return silk, velvet, damask, satin, taffeties, and rice. To Switzerland they sent coarse cloth, hats, sufficient wine, oil, soap, and mercury, and received from thence cheese, linen, and, in time of war, horses. The great towns of Germany purchase from Lyons, besides the same merchandise as the Swiss, stuffs of gold and silver. From Holland, Lyons took more merchandise than that which it sent in return. With the other parts of France it carried on a very considerable trade. Lyons reckoned eleven parishes, six gates, four faubourgs, and was divided into thirty-five districts, named "Parronages." The cathedral church was a magnificent Gothic building; the town-house is esteemed one of the most beautiful in Europe; and its other public buildings, before the revolution, were four abbeys, fifty con-

vents, three public schools, a college of physic, two general hospitals, &c.; and, besides these, an academy of sciences, instituted A. D. 1707, and an academy of fine arts, established in 1724, both which were united in 1758, a society of agriculture, a veterinary school, a theatre, a public library, seventy companies of tradesmen and artists, three forts, an arsenal well supplied and carefully arranged, an infirmary, five hundred feet in length, &c. to all which we may add magnificent quays. At an early period of the revolution, an union was formed between the towns of Lyons, Marseilles and Toulon, under the title of "Federal Republicanism," contrary to the sense of the nation, which inclined to favour a republic one and indivisible. Lyons contained a great number of disaffected persons, both Royalists and Girondists, and was declared to be in a state of rebellion. After a siege of two months, during which it is supposed to have lost 2000 men, and a great part of the city was reduced to ashes, Lyons surrendered, and many of the rebels who were not able to escape were taken and executed. By a decree of the convention, the walls and public buildings of Lyons were ordered to be destroyed, and the name of the city itself to be changed to that of "Ville Affranchie;" but this decree was afterwards repealed. It is stated to contain 179,570 inhabitants, and the six cantons, into which it is divided, to include 123,517, on a territory of 55 kilometres, in four communes. N. lat. $45^{\circ} 44'$. E. long. $4^{\circ} 50'$.

LYONS, a village of America, in Ontario county, and township of Phelps, in New York, at the junction of Mud and Canandarque creeks; 16 miles N. of Geneva, and about 25 S. of Sodus; situated in a fine country, and accommodated with excellent advantages for water-conveyance.

LYONSIA, in *Botany*, serves to commemorate Mr. Israel Lyons, born at Cambridge in 1739, being the son of a Polish Jew, settled there as a silversmith; who published "A Hebrew Grammar," and "Observations and Enquiries relating to various Parts of Scripture History." He was distinguished as a mathematician and botanist, and had the honour of instructing in the latter science the celebrated sir Joseph Banks, by whose recommendation he read a course of lectures on Botany at Oxford, where such a course was then much wanted. He died in London of the measles, about two years after he had accompanied Captain Phipps, afterwards lord Mulgrave, towards the north pole, in 1773. For some time he was employed as one of the calculators of the Nautical Almanac, for which he received an annual salary of an hundred pounds; and at the time of his death he was preparing for the press a complete edition of all the works of Dr Halley. Besides several mathematical works, among which we may reckon his "Fluxions," published in 1758; he had in contemplation a *Flora Cantabrigiæ*; but published only a "*Epitulus*" of plants discovered in that neighbourhood since the time of Ray, in 1763, in 8vo. Brown. Prodr. Nov. Holl. v. 1. 460. Wern. Transf. v. 1. 69.—Chais and order, *Pentstemon Monosylla*. Nat. Ord. *Centauræ*, Linn. *Aj. cinæ*, Just Brown.

Ess. Ch. Corolla funnel-shaped; its mouth and tube without scales; limb in five deep, recurved, equilateral segments. Stamens prominent; filaments thread-shaped, inserted into the middle of the tube; anthers arrow-shaped, enlarging with the stigma by the middle, their hind lobes void of pollen. Germen of two cells; style one, thread-shaped, dilated at the top; stigma somewhat conical. Scales at the base of the germen combined. Capsule cylindrical, of two cells, its valves like folicles, with a parallel distinct partition, bearing the seeds on each side upon fixed receptacles.

1. *L. pratincola*, the only species, gathered by Mr. Brown

at Port Jackson, and in Van Diemen's land. A climbing shrub, with opposite leaves. Cymes terminal, three forked. Flowers among the smallest of this tribe, their limbs bearded.

LYPERANTHUS, from *λυπερ*, sadness, and *ανθος*, a flower, because of the very dark-red gloomy hue of the blossoms, which is unusual in this tribe.—Brown Prodr. Nov. Holl. v. 1. 325.—Class and order, *Gynandria Monandria*. Nat. Ord. *Orchideae*.

Gen. Ch. Cal. Perianth superior, ringent, of three leaves, the upper one vaulted, the rest flattish. Cor. Petals two, nearly equal and similar to the flatter calyx-leaves. Nectary shorter, its edges ascending, hood-like, with a taper point, the disk glandular or papillary. Stam. Anther terminal, permanent, its cells close together; masses of pollen two in each cell, powdery. Pist. Germen inferior; style columnar, linear. Peric. Capsule. Seeds numerous.

Eff. Ch. Calyx ringent; its upper leaf vaulted. Lip shorter, hooded, glandular, with a taper point. Style linear. Anther vertical, permanent.

A genus of smooth *Orchideae*, growing on the ground. Bulbs naked, undivided, terminating the descending caudex, which throws out roots above them. Stem bearing a single leaf close to the root, and two bractees above, besides what accompany each flower. Flowers racemose, very dark red, mostly reversed.

1. *L. suaveolens*. Leaf linear, elongated. Petals ascending. Disk of the nectary bearing rows of sessile glands; its margin naked.—Found near Port Jackson, New South Wales.

2. *L. ellipticus*. Leaf lanceolate-elliptical. Disk of the nectary papillary; its margin naked.—Gathered by Mr. G. Caley in the same neighbourhood.

3. *L. nigricans*. Leaf ovate, somewhat heart-shaped. Petals divided. Lip fringed; its disk papillary.—Found by Mr. Brown near Port Jackson, as well as in the southern part of New Holland.

LYRA, in *Anatomy*, a name applied to a certain part of the brain. See **BRAIN**.

LYRA, in *Astronomy*, a constellation in the northern hemisphere.

The number of its stars, in Ptolemy's catalogue, is ten; in Tycho's, eleven; in Hevelius's, seventeen; and in the Britannic catalogue, twenty-one. See **CONSTELLATION**.

LYRA, **NICHOLAS DE**, in *Biography*, a learned French monk and commentator on the scriptures in the thirteenth and fourteenth centuries, was born in a small town in the diocese of Evreux, in Normandy. He was descended from Jewish parents, but becoming a Christian, he embraced a religious life in a monastery at Verneuil, in 1291. Having remained there some time, he was sent to Paris, where he applied with the greatest diligence to his studies, and was admitted to the degree of doctor. He died in this city in the year 1340. He was author of "Poeticals," or a compendium of the whole bible, which he began in 1293, and finished in the year 1330. The first edition of this work was published at Rome in 1472, in seven volumes folio, and is now become rare; but it has since undergone various impressions at Basil, Lyons, Doway, Antwerp, &c. of which the best is said to be that of Antwerp in 1634, in six volumes folio. De Lyra was also the author of "Moral Commentaries upon the Scriptures;" "A Disputation against the Jews;" and other pieces. Moreri.

LYRA, in *Ichthyology*, the name of a fish of the *trigla* kind, of which there are two varieties, reckoned by Artedi and Linnæus two different species. The one is the *piper* (see **TRIGLA Lyra**), the other, the *lyra cornuta*, or horned harp-fish. This last is a fish of an octangular form, covered

all over with bony scales; these are of a rhomboidal figure, and each has in its middle a sharp and strong prickle bending backwards: it is of a red colour, and its head is very large; its snout divides towards the extremity into two long horns, on which are placed two perpendicular spines, and a third above makes an acute angle with these; it has one very long fin on the back, and another answering to it behind the anus: also two large ones at the gills, and two smaller on the belly; it has only two filaments, called fingers, behind its gill-fins; its mouth is large, but has no teeth, and there are several beards on its under jaw; two of which are longer than the rest, and are branched: it is caught in the Mediterranean, and brought to market at Rome; it is a scarce fish in other places, and at Montpellier was once shewn to Mr. Ray for the remora. See **TRIGLA Cataphracta**.

LYRA is also a species of *Callionymus*; which see. See **DRAGONET**, under which article the other species of the *callionymus* are described.

LYRA is also the name of a beautiful sea-shell of the genus of the concha globosa, or dolium. There are three species of the lyra, or harp-shell. 1. The common lyra, which has thirteen rose-coloured ribs running along its body. 2. The eleven-ribbed lyra; and 3. The noble harp, or *lyra nobilis*. This is a most elegantly variegated shell; its ground colour is a deep brown, and its variegations very elegant and black. See **CONCHOLOGY**.

LYRE Lucida. See **LUCIDA**.

LYRATUM FOLIUM, in *Botany*. See **LEAF**.

LYRE, *Λύρα*, *Lyra*, in the *Ancient Music*, a musical instrument of the string kind, so dear to the Greeks, that they have by turns attributed its invention to Mercury, Apollo, Linus, Orpheus, and Amphion: making it the symbol of all excellence in poetry and music. The poets and historians of fabulous times, however, seem most to agree in ascribing the invention to Mercury. And among the accounts of the several writers of antiquity who have mentioned this circumstance, and confessed the invention to the Egyptian Mercury, that of Apollodorus (*Bibliotheca*, lib. ii.) seems the most intelligible and probable. "The Nile," says this writer, "after having overflowed the whole country of Egypt, when it returned within its natural bounds, left on the shore a great number of dead animals of various kinds, and, among the rest, a tortoise, the flesh of which being dried and waited by the sun, nothing was left within the shell but nerves and cartilages, and these being braced and contracted by desiccation, were rendered sonorous; Mercury, in walking along the banks of the Nile, happening to strike his foot against the shell of this tortoise, was so pleased with the sound it produced, that it suggested to him the first idea of a lyre, which he afterwards constructed in the form of a tortoise, and strung it with the dried sinews of dead animals."

Censorinus, however (*De Die Nat.* cap. 22.), attributes to Apollo the first idea of producing sound from a string, which was suggested to him by the twang of his sister Diana's bow. *Ψαλλειν* is strictly to twang a string, and *Ψαλλειν* the sound which the bow-string produces at the emission of the arrow. Euripides in *Bacch.* v. 782. uses it in that sense,

"Ψαλλειν τὴν νῆρον."
Ψαλλειν τὴν νῆρον.

"Who twang the nerve of each elastic bow."

Father Montfaucon says it is very difficult to determine in what the lyre, cithara, chelys, psaltery, and harp differed from each other; as he had examined the representations of six hundred lyres and citharas in ancient sculpture, all which

he found without a neck, and the strings open as in the modern harp, played by the fingers. (Antiq. Expl. tom. iii. lib. 5. cap. 3.) But though ancient and modern authors usually confound these instruments, yet a manifest distinction is made by Arist. Quintil. in the following passage, p. 101. After discussing the characters of wind-instruments, he says, "Among the stringed instruments, you will find the lyre of a character analogous to *masculine*, from the great depth or gravity, and roughness of its tones; the sambuca of a *feminine* character, *weak* and *delicate*, and from its great *acuteness*, and the fineness of its strings, tending to *dissolve* and *enervate*. Of the intermediate instruments, the polyphthongum *partakes* most of the *feminine*; but the cithara *differs* not much from the *masculine* character of the lyre." Here is a scale of stringed instruments: the lyre and sambuca at the extremes; the polyphthongum and cithara between; the one next to the sambuca, the other next to the lyre. He afterwards just mentions that there were others between these. Now it is natural to infer, that as he constantly attributes the manly character to gravity of tone, the cithara was probably the more acute instrument of the two: less loud and *rough*, and stringed with smaller strings. Concerning what difference there might be in the form and structure of the instruments, he is wholly silent. The passage, however, is curious as far as it goes, and decisive. The cithara may, perhaps, have been as different from the lyre, as a single harp from one that is double; and it seems to be clearly pointed out by this multiplicity of names that the Greeks had two principal species of stringed instruments; one, like our harp, of full compass, that rested on its base; the other more portable, and slung over the shoulder, like our smaller harp or guitar, or like the ancient lyres represented in sculpture.

Tacitus, Annal. xvi. 4. among the rules of decorum observed by public performers, to which Nero, he says, strictly submitted, mentions, "That he was not to sit down when tired." Ne fessus resideret. It is remarkable that he calls these rules, *Cithara Leges*, "The Laws of the Cithara;" which seems to afford a pretty fair proof of its being of such a size and form as to admit of being played on *standing*.

The use of the phorminx in Homer, leads rather to the rough, manly, harp-like character. But a passage in Orpheus, Argon. 580, seems to make phorminx the same as cithara, the lustful instrument of Mercury. It is there said of Chiron, that he "sometimes strikes the cithara of Apollo: sometimes the shell-resounding phorminx of Mercury,"

"Αλλ' οτε δ' αὖτε τὸν κίθαριν ἢ φάρμινχον ἀνέχετο,
ἢ φάρμινχον ἢ κίθαριν ἢ φάρμινχον ἢ κίθαριν."

This passage is curious; for though the Argonautics were not written by Orpheus himself, they have all the appearance of great antiquity.

The belly of a theorbo, or arch-lute, is usually made in the shell-form, as if the idea of its origin had never been lost; and the etymology of the word guitar seems naturally deducible from cithara; it is supposed that the Roman C was hard, like the modern K, and the Italian word *chitarra* is manifestly derived from *κίθαρη*, *cithara*.

In the hymn to Mercury, ascribed to Homer, Mercury and Apollo are said to play with the cithara *under their arm*, ver. 507. ὑπὸ τῷ ὤμῳ κίθαριν ἔχοντες, *sub ulna cithara habuit*, "played with the cithara *under his arm*." So in ver. 472. ὑπὸ τῷ ὤμῳ, *at his arm, should*, according to the critics, be *brachium*, as it is afterwards. This seems to point out a guitar more than a harp; but the ancients had lyres, citharas,

and testudos of as different shapes from each other, as our harp, spinnet, virginal, and pianoforte.

These passages in old authors are a kind of antique drawings, far more satisfactory than those of ancient sculpture; for we have seen the syrinx, which had a regular series of notes ascending or descending, represented with seven pipes, four of one length, and three of another, which of course would furnish no more than two different sounds. The cymbals too, which were to be struck against each other, are placed in the hands of some antique figures in such a manner, that it is impossible to bring them in contact with the necessary degree of force, without amputating, or at least violently bruising the thumbs of the performer. And it is certain that artists continued to figure instruments in the most simple and convenient form for their designs, long after they had been enlarged, improved, and rendered more complicated. An instance of this in our own country will confirm the assertion. In the reign of George II. a marble statue was erected to Handel, in Vauxhall gardens. The musician is represented playing upon a lyre. Now if this statue should be preserved from the ravages of time and accident 12 or 1400 years, the antiquaries will naturally conclude that the instrument upon which Handel acquired his reputation was the lyre; though we are at present certain that he never played on, or even saw a lyre, except in wood or stone.

In one of the ancient paintings at Portici, we saw a lyre with a pipe or flute for the cross bar, or bridge at the top. Whether this tube was used as a flute to accompany the lyre, or only a pitch-pipe, we know not; nor in the course of our enquiries has any similar example of such a junction occurred elsewhere.

Brossard seems to have abridged the history and progress of the lyre chronologically in the most short and clear manner, which Grassineau has spun out to great length by jumping from one century to another, and crowding together all the wild and incoherent stories relative to the lyre, its inventors and performers, that he could find. All that the diligent and generally accurate Brossard says on the subject is, that the lyre was a stringed instrument, upon which the whole musical system of the ancients has been built. It is pretended that Mercury first invented it by chance, and that it had only then three strings, which consisted of B C D; that Apollo added a fourth, Corcebus, a fifth, Hyagnis, a sixth, and Terpander, a seventh. It remained in this state till the time of Pythagoras, or, according to others, Lycaon added to it an eighth string, to render the extremities *consonant*. Timotheus afterwards added a ninth, tenth, and eleventh string. Others after him increased the number to sixteen, that is, fifteen principals, and one added, which will be explained in the articles PROSLAMEANOMINES and SYSTEM: which see.

Mr. Barnes, in the prolegomena to his edition of Anacreon, has an inquiry into the antiquity and structure of the lyre; of which he makes Jubal the first inventor. For the several changes this instrument underwent, by the addition of new strings, he observes, that, according to Diodorus, it had originally only three, referring to the three seasons of the year, as the Greeks counted them, *viz.* spring, summer, and autumn; whence it was called *τρίχορδος*. Afterwards it had seven strings; as appears from Homer, Pindar, Horace, Virgil, &c. Festus Avienus gives the lyre of Orpheus nine strings. David mentions an instrument of that sort stringed with ten, in *psalterio decachordo*. Timotheus of Miletus added four to the old seven, which made eleven. Josephus, in his Jewish Antiquities, makes mention of one with twelve strings; to which were afterwards added six others, which

which made eighteen in all. Anacreon himself says, p. 253, of Mr. Barnes's edition, *canto viginti totis chordis*. As for the modern lyre, or Welsh harp, it is sufficiently known. (See HARP.) From the lyre, which all agree to be the first instrument of the stringed kind in Greece, there arose an infinite number of others, different in shape and number of strings; as the psalterium, trigon, sambucus, pectis, magadis, barbiton, teltudo (the two last used promiscuously, by Horace, with the lyre and cithara), epigonium, simmicium, and pandura; which were all struck with the hand, or a plectrum. See PSALTERY, SAMBUCA, MAGADIS, BARBITON, and CITHARA.

LYRE, *Lydian*. See LYDIAN LYRE.

LYRE of the *Musevites*. This is a rude and coarse instrument, in the form of the ancient lyre of six strings, as thick as packthread, which are thrummed with the naked fingers after the manner of the lute.

LYRE, among painters, statuary, &c. is an attribute of Apollo and the Muses.

LYRIC, something sung or played on the lyre or harp.

LYRIC is more particularly applied to the ancient odes and stanzas; which answer to our airs or songs, and may be played on instruments. See the next article.

LYRIC Poetry, verses written for music; which, with the ancients, implied verses to be sung to the accompaniment of the lyre. In the supplement to the first edition of the folio Encyclopédie, there is a very long article on the subject. We have often admired the ingenuity, refinement, and apparent feeling, with which the French treat the subject of dramatic music. Even in the feuds and discussions of the Gluckists and Piccinists, many of the tracts and pamphlets seem to breathe the purest taste and most profound reasoning of which the theme is capable. The Italians, who have so long furnished models of perfection to the rest of Europe in composition and performance, have not half so much to say in defence of their talents as the French in attacking them.

The article Lyric Poetry in the supplement to the first edition of the Encyclopédie, written long before the firm adherents to Lulli and Rameau were extinct, is of great length, and seems to flow from a writer who had read, meditated, and felt, with enthusiasm, all the inspirations of the lyric bards of Greece. He has taken a wide range in treating the subject, and considered the union of poetry and music, not only with more enlarged views than any other modern, but perhaps than the ancients themselves. He begins in the following manner: "The lyric poetry of the Grecians was not only sung, but composed to the chords of the lyre. This was at first the characteristic distinction of all that was called lyric poetry by the Romans, and their descendants and imitators in later times. The poet was a musician, he called upon the god of verse, and animated himself with a prelude. He fixed upon the time, the movement, and the musical period; the melody gave birth to the verse; and thence was derived the unity of rhythm, character, and expression, between the music and the poem that was sung. Thus the poetry became naturally subservient to number and cadence, and thus each lyric poet invented not only the proper kind of verse, but also the strophe analogous to the melody which he himself had created, and to which he composed it.

"In this respect, the lyric poem or ode with the Latins and with modern nations, has been nothing more than a frivolous imitation of the lyric poem of the Greeks: they say, *I sing*, but never do sing; they speak of the chords of the lyre, but have never seen a lyre. No poet, since Horace inclusively, appears to have modelled his odes upon

a melody. Horace adopting, by turns, the different formulae of the Greek poets, seems so much to have forgotten that an ode ought to be sung, that he has often suspended the sense at the end of the strophe, where the air ought to repose, to the beginning of the next stanza."

This species of poetry was originally employed in celebrating the praises of gods and heroes; though it was afterwards introduced into feasts and public diversions: it is a mistake to imagine Anacreon, as the Greeks do, the author of it; since it appears from scripture to have been in use above a thousand years before that poet. Mr. Barnes shews how unjust it is to exclude heroic subjects and actions from this sort of verse, lyric poetry being capable of all the elevation and sublimity such subjects require; which he confirms by the examples of Alcaeus, Sappho, Anacreon, and Horace, and by his own essay, a triumphal ode inscribed to the duke of Marlborough, at the head of this edition: he concludes with the history of lyric poetry, and of those ancients who excelled in it.

The characteristic of lyric poetry, which distinguishes it from all others, is *dignity and sweetness*. As *gravity* rules in heroic verse; *simplicity*, in pastoral; *tenderness* and *softness*, in elegy; *sharpness* and *poignancy*, in satire; *mirth*, in comedy; the *pathetic*, in tragedy; and the *point*, in epigram; so in the lyric, the poet applies himself wholly to soothe the minds of men, by the sweetness and variety of the verse, and the delicacy and elevation of the words and thoughts; the agreeableness of the numbers, and the description of things most pleasing in their own nature. See ODE and POETRY.

LYRODI, among the *Ancients*, a kind of musicians who played on the lyre, and sung at the same time.

LYRODI was also an appellation given to such as made it their employment to sing lyric poems, composed by others.

LYS, in *Geography*, one of the 13 departments of the region of France, called the Reunited Country, formed of a part of Austrian Flanders; bounded on the N. by the sea, and on the E. by the department of the Escaut, in N. lat. 51°. It contains 3662½ kilometres, or 150 square leagues, and 470,707 inhabitants. It is divided into four circles or districts, 36 cantons, and 250 communes. Its circles are Bruges, containing 149,421 inhabitants, Furnes, 49,808, Ypres, 107,103, and Courtray, 164,375. The annual contributions amount to 4,915,251 fr. and the annual expenses for government, the administration of justice, and public instruction, amount annually to 358,916 fr. 66 cents. The capital of this department is Bruges. The soil, in general, is fertile, and produces all sorts of grain, flax, tobacco, and excellent pastures.

LYS, *Sz.*, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Muret; 7 miles W. of Muret. The place contains 1140, and the canton 5249 inhabitants, on a territory of 190 kilometres, in 11 communes.

LYSANDER, a township of America, in Onondago county, New York, incorporated in 1794, and comprehending the military towns of Hannibal and Cicero. The number of inhabitants is 121. It is distant 16 miles S.E. of lake Ontario.

LYSANDER, in *Biography*, an eminent Spartan commander in the last years of the Peloponnesian war, was the son of Aristoclitus, a descendant of the Heracleidae, but not of the royal line. About the year 406 B.C. Lysander was made the naval commander of the Lacedæmonians. His first measure was to draw off Ephesus from the interest of Athens, which he accomplished, and at the same time gained the friendship of Cyrus the younger. He gave battle to the Athenian fleet, consisting of 120 ships, at

Ægos-Potamos, in the Thracian Chersonesus, and wholly destroyed it except three ships, with which the enemy's general fled to Evagoras, king of Cyprus. In this celebrated battle, which happened 405 years before the Christian era, the Athenians lost 3000 men, and with them their empire and influence among the neighbouring states. Lyfander knew how to take advantage of this victory, and in the following year Athens, worn out by a long war of 27 years, gave itself up to the power of the enemy, and submitted, in every respect, to the power of Lacedæmon. The government of Athens was totally changed, and 30 tyrants were set over it by Lyfander. This success, and the honour of having put an end to the Peloponnesian war, rendered the conqueror extremely proud, and ambitious of higher distinctions than the constitution of his country would allow. He aimed at universal power, by establishing aristocracy in the Grecian cities of Asia, and he attempted to make the crown of Sparta elective, in order that he might seize it for himself, but was, in this respect, unsuccessful, and he was accused of gross corruption in endeavouring to accomplish his purposes. The sudden declaration of war against the Thebans saved him from the accusations of his adversaries, and he was sent with Pausanias against the enemy. The Spartan troops were defeated, and their general Lyfander killed in the year B.C. 394. His body was recovered by his colleague Pausanias, and honoured with a magnificent funeral. Lyfander was a brave man, but his ambition merited the severest censure. He was arrogant and vain in his public, as well as in his private conduct, and he received and heard with the greatest avidity the hymns which his courtiers and flatterers sung to his honour. But in the midst of all his pomp, his ambition, and his intrigues, he died extremely poor, and on account of his poverty his daughters were rejected by two opulent citizens of Sparta, to whom they had been betrothed during the life of their father. Plutarch. Cornelius Nepos. Anc. Univer. Hist.

LYSANDRIA, *Λυσανδρία*, in *Antiquity*, a Samian festival, celebrated with sacrifices and games in honour of Lyfander, the Lacedæmonian admiral. It was anciently called *heræa*, which name was abolished by a decree of the Samians.

LYSANO, in *Geography*, a town of Prussia, in the palatinate of Culm; 15 miles S. of Culm.

LYSE, a town of Norway; 8 miles S.S.W. of Bergen.

LYSEKIL, a sea-port town of Sweden, in the province of West Gothland; 16 miles W. of Uddevalla.

LYSERUS, POLYCARP, in *Biography*, a learned Lutheran divine, was born at Winendeen, in Germany, in 1552. He was educated at the expense of the prince of Wittemburg, and was distinguished as well for great industry as considerable talents. He became distinguished as a preacher, and received frequent applications to preach, on particular occasions, at Vienna, and in other parts of Austria. In 1576 he took his degree of doctor of divinity, and in the following year, Augustus, elector of Saxony, was induced, by the fame of his pulpit talents, to appoint him a minister of the church of Wittemburg. He was soon raised to the professorship of divinity in the university, and attained to other high honours. In the year 1594, he was appointed minister of the court of Dresden, where he spent the remainder of his life, occupied not only in literary labours, and in ministerial duties, but in the education of young princes. He died in 1601, in the forty-ninth year of his age. He was a very voluminous writer, particularly as a commentator on the scriptures. He wrote likewise several controversial treatises.

LYSERUS, JOHN, a Lutheran divine of the same family, distinguished for his vast zeal as a writer in defence of polygamy. The most considerable of his publications is entitled "Polygamia Triumphatrix," &c. He spent his fortune and his life in endeavours to maintain and propagate his favourite doctrine, and with incredible pains travelled through almost every country on the European continent, examining libraries for materials to confirm his system. At length, having spent all his property, and being reduced to great distress, he died in the neighbourhood of Paris in 1684. Moreri.

LYSIANTHUS, in *Botany*. (See LISIANTHUS.) The latter is, no doubt, the original reading in Browne's Jamaica. Lamarck adopts the former, apparently from *λύσις*, a dissolver, alluding to the deobstruent or purgative qualities of some of the species described by Aublet.

LYSIARCHA, an ancient kind of magistrate, being the pontiff of Lycia, or superintendant of the sacred games of that province.

Strabo observes, that the lyfiarcha was created in a council consisting of the deputies of twenty-three cities; that is, of all the cities in the province; some of which cities had three voices, others two, and others but one.

Cardinal Norris says, that the lyfiarcha presided in matters of religion; in effect, the lyfiarcha was nearly the same with the *afiarcha*, and *fyriarcha*; who, though they were all the heads of the councils, or states of those provinces, yet were they established principally to take care of the games and feasts celebrated in honour of the gods, whose priests they were inaugurated, at the same time that they were created *lyfiarcha*, *fyriarcha*, or *afiarcha*.

LYSIAS, in *Biography*, an eminent Greek orator, born at Syracuse about the year 459 B.C. He accompanied his father to Athens while he was very young, and was educated with great care in that city. In process of time he became himself a teacher of rhetoric, and composed orations for others, but does not appear to have been a pleader. He distinguished himself by the eloquence and purity of his orations, of which it is said by Plutarch, he wrote no less than 425, though the number may with more probability be reduced to 230; and of these only 34 remain, which are to be found in the collections of the Greek orators. He died in the 81st year of his age, and in the 378th year B.C. Lysias attained great reputation in his time, which his works afterwards supported, and he is mentioned with applause by Cicero and Quintilian. Lysias lived at a somewhat earlier period than Isocrates; and exhibits a model of that manner which the ancients call the "tenuis vel subtilis." He has none of the pomp of Isocrates. He is every where pure and attic in the highest degree; simple and unaffected; but wants force, and is sometimes frigid in his compositions. In the judicious comparison which Dionysius of Halicarnassus makes of the merits of Lysias and Isocrates, he ascribes to Lysias, as the distinguishing character of his manner, a certain grace or elegance arising from simplicity: "περί τε γὰρ ἡ Λυσίας λέγεται ἔχειν τὸ χαλεπὸν ἢ δ' ἱσοκράτης; βέλτερον: i. e. the style of Lysias has gracefulness for its nature; that of Isocrates seems to have it." In the art of narration, as distinct, probable, and persuasive, he holds Lysias to be superior to all orators; at the same time he admits, that his composition is more adapted to private litigation than to great subjects. He convinces, but he does not elevate nor animate. The magnificence and splendour of Isocrates are more suited to great occasions. He is more agreeable than Lysias; and in dignity of sentiment, far excels him. Blair's Lect. vol. ii. The best editions of Lysias's

Lyfias's orations is that by Taylor, London, in 1739, and Cambridge 1740.

LYSIA, in *Ancient Geography*, a town of Asia, in Syria, seated on the river Marfyas, W. of the river Orontes, and N.W. of the town of Apamea.—Also, a town of Asia Minor, in Caria, placed by Ptolemy in Phrygia Major.—Also, a town of the Peloponnesus, in Arcadia, called also *Lufias*.

LYSIMACHIA, in *Botany*, a very ancient generic name, and so called, according to Pliny and Ambrosinus, from Lysimachus, a favourite general of Alexander the Great, who was afterwards king of Thrace. The English name of this plant, *Loosestrife*, is evidently taken from *λυσις*, a dissolution of strife, or a peacemaker, but how this title could apply to the king on whom it was bestowed, and who appears to have been of a cruel and ferocious temper, we are at a loss to imagine, unless it were like the ludicrous derivation of *lucus*, a non lucendo. Linn. Gen. 83. Schreb. 109. Willd. Sp. Pl. v. 1. 816. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 227. Ait. Hort. Kew. ed. 2. v. 1. 314. Brown. Prod. Nov. Holl. v. 1. 428. Tournef. t. 59. Juss. 95. Lamarck Illustr. t. 101. Gartn. t. 50.—Class and order. *Pentandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Lysimachia*, Juss.

Gen. Ch. Cal. Perianth inferior, five-cleft, acute, erect, permanent. Cor. of one petal, wheel-shaped; tube none; limb in five, ovate-oblong, deeply cloven segments. Stam. Filaments five, awl-shaped, opposite to the segments of the corolla, mostly united at the base; anthers acuminate. Pist. Germen superior, roundish; style thread-shaped, the length of the stamens; stigma obtuse. Peric. Capsule globose, mucronated, of one cell and ten valves. Seeds numerous, angular. Recept. globose, very large, dotted.

Ess. Ch. Corolla wheel-shaped. Capsule globose, pointed, with ten valves.

Obf. L. *Linum-stellatum* has fruit with only five valves.

Nearly the whole of this genus is pretty well known in our gardens, whilst some of its species are found to grow spontaneously in our hedges and fields. It is divided into two sections, the first of these having many flowers on a stalk, the second composed of such as are single-flowered.—Of the first section are the following.

L. *vulgaris*. Yellow Loosestrife. Linn. Sp. Pl. 209. Engl. Bot. t. 761. Curt. Lond. fasc. 5. t. 19.—Panicked. Clusters terminal. Leaves ovate-lanceolate, acute.—A native of shady, watery places on the banks of rivers, flowering in July.—Root perennial, creeping. Stems erect, three feet high, leafy, many-flowered. Leaves opposite, often three or four together, spreading, veiny, smooth, sometimes downy. Clusters erect, each partial flower-stalk with an awl-shaped bractea at its base. Flowers yellow and handsome.

L. *thyrsiflora*. Tufted Loosestrife. Linn. Sp. Pl. 209. Engl. Bot. t. 176.—Flowers in lateral, pedunculated clusters.—This extremely rare plant, when it does occur, may be found in damp, watery situations, in particular parts of Yorkshire and Scotland. It flowers in July.—Root perennial, creeping. Stems erect, a foot and half high, perfectly simple, round, leafy, smooth, now and then woolly. Leaves opposite, sessile, acute, entire, smooth. Flowers in axillary, dense clusters, small, of a less brilliant colour than the last. Many parts of the herbage and inflorescence are prettily spotted with red.

Of the remaining species belonging to this section, as they are detailed in Willdenow, none are natives of Britain. They are called L. *decurrens*, *Ephemerum*, *atropurpurea*, *dubia*, and *stricta*.

The second section comprises, amongst others, the following:

L. *memorum*. Yellow Pimpernel, or Wood Loosestrife. Linn. Sp. Pl. 211. Engl. Bot. t. 527. Curt. Lond. fasc. 5. t. 18.—Leaves ovate, acute. Flowers solitary. Stem procumbent. Stamens smooth.—Found not unfrequently in groves and moist shady places, flowering from May to September.—Roots perennial. Stems procumbent, creeping, branched, square, reddish, shining, leafy. Leaves opposite, on footstalks, ovate, entire, smooth. Stalks axillary, solitary, single-flowered, slender. Flowers delicate, yellow.—This and the following species may be regarded as two of our most ornamental common plants, more especially as their myrtle-like herbage, when intermixed or entangled with ferns or moss, gives a pleasing variety to the verdure of rocks, and the banks of rivulets, or shady ponds.

L. *Nummularia*. Moneywort, or Herb Twopence. Creeping Loosestrife. Linn. Sp. Pl. 211. Engl. Bot. t. 528. Curt. Lond. fasc. 3. t. 14.—Leaves somewhat heart-shaped. Flowers solitary. Stem creeping. Stamens glandular.—A native of the banks of ditches and very moist meadows. It flowers copiously during the summer. Root perennial. Stems prostrate, square, compressed, generally simple. Leaves opposite, on footstalks, heart-shaped or roundish, waved, palish green. Corolla pale lemon-coloured, and, when magnified, clothed with small glands standing on footstalks, as are also the stamens.—The qualities both of this and the preceding are to the best of our knowledge perfectly unimportant either for medicinal or agricultural purposes.

The remaining species of *Lysimachia* are none of them natives. We therefore select two or three of the more interesting exotic ones.

L. *punctata*. Four-leaved Loosestrife. Linn. Sp. Pl. 210. Jacq. Austr. t. 366.—Leaves generally four together, almost sessile. Stalks verticillate, single-flowered.—Found amongst reeds in Holland, Austria, and other parts of Europe, flowering in July and August. Root perennial, somewhat creeping and fibrous. Stems two or three feet high, upright, downy, leafy, generally simple. Leaves ovate-lanceolate, entire, frequently spotted with black on the lower side. Flowers rather small, yellow. The segments of the corolla pointed, with tawny dots at their base.

L. *quadriflora*. Four-flowered Loosestrife. Ait. Hort. Kew. n. 7. Sims in Curt. Mag. t. 660.—Leaves opposite, sessile, linear, very long. Stalks four together, terminal, single-flowered.—Sent from North America to Kew garden by Mr. Francis Masson in 1798. It flowers like the last in July and August.—Root perennial. Stems quadrangular, much branched. "Leaves opposite, linear, quite entire, smooth, sessile, longer than the branches. Branches axillary to the leaves, similar, terminated with four leaves crossed, serving the office of bracteas; from the axils of each of these there rises a flower-stalk, bearing a solitary flower, nodding." The segments of the corolla are crenate and very sharply pointed, of a beautiful bright yellow colour; whilst the whole herbage is of a dark, blackish-green. It is a hardy perennial, requiring no particular treatment, even bearing the smoke of London without much injury.

L. *ciliata*. Ciliated or Fringed Loosestrife. Linn. Sp. Pl. 210. (*Lysimachia canadensis* lutea, folio Jalapæ: Walth. Hort. t. 12.)—Leaf-stalks fringed. Flowers drooping.—A native of North America, whence it was introduced by Mr. Philip Miller into this country in 1732. It flowers in July and August.—Root perennial, creeping. Stems about two feet high, erect. Leaves oblong, smooth, acuminate, veined

veined underneath. *Flowers* axillary, yellow, each on a long, slender, naked stalk. Linnæus in his *Système Végétal* reckons *L. ciliata* as a variety only of *las quadrifolia*, and in this he is followed by Willdenow, but on the authority of the *Species Plantarum* and *Hortus Kewensis*, we are inclined to consider them as distinct.

L. Linum-stellatum. Small Looselife. Linn. Sp. Pl. 211. (*Linum minimum stellatum*; Magnol. Bot. Mouss. t. 162.) —Calyx longer than the corolla. Stem erect, very much branched.—Not uncommon in France and Italy, where it flowers in the spring. Root annual, capillary, whitish. Stem about two or three inches high, very slender, much branched. Leaves sessile lanceolate, pointed, entire. Flowers small, of a pale green colour.

Mr. R. Brown, Prod. Nov. Holl. v. 1. 428, suggests that this genus ought certainly to be divided. He describes one species as found near Port Jackson, *L. maculata*, downy, with ovate leaves, and axillary flowers, whose stalks are shorter than the footstalks. There is no absolute certainty of this being distinct from *L. japonica* of Thunberg.

LYSIMACHIA, in *Gardening*, comprehends plants of the hardy, herbaceous, biennial, and perennial sorts, of which the species mostly cultivated are, the willow-leaved loosestrife (*L. ephemerum*); the purple flowered loosestrife (*L. dubia*); and the upright loosestrife (*L. stricta*.)

Method of Culture.—All these plants may be readily increased, either by sowing the seeds in the autumnal season, as soon as they become fully ripe, on a moist border which has an eastern aspect; or by parting the roots, and planting them out at the same season in similar situations. The plants should afterwards be kept perfectly clean, and where the first mode is used, removed into the places where they are to remain during the autumn.

But in the second kind the seeds should be sown upon a hot-bed.

The third sort is best increased by planting the bulbs thrown out from the axils of the leaves.

Each of these different plants may be employed by way of ornament and variety in the clumps, borders, and other parts of gardens and pleasure grounds.

LYSIMACHIA, in *Ancient Geography*, a town of Thrace, called in the time of Ptolemy *Xanthum*.

LYSIMACHIA *Worm*, in *Natural History*, a name given to an insect found very frequently feeding on the leaves of the *Lyfimachia*, or willow-herb. It has usually been esteemed a caterpillar, but is properly one of the faultless chenilles, having a rounded head, and twenty-two legs; this creature changes its skin several times, and finally changes its colour with it; it is at first of a blueish-grey, but on its last change in the worm-state it becomes of a yellowish-green; when it has lived a week, or thereabout, after this last change, it becomes a chrysalis, from which there afterwards comes out a four-winged fly.

LYSIMACHIE, in *Botany*, an elegant Natural Order of plants, named from the *Lyfimachia*, which is one of them; see that article. This order is the first in Jussieu's eighth class. See LABIATÆ and GENTIANÆ.

The *Lyfimachia* is thus defined.

Calyx divided. *Corolla* generally regular, its limb divided, mostly into five lobes. *Stamens* definite, mostly five, rarely either more or fewer, being equal in number to, and placed against, the segments of the corolla. *Style* solitary; style simple, or rarely clove. *Fruit* of one cell with many seeds, often capsular, the receptacle of the seeds central, unconnected with the valves. *Stem* herbaceous. *Leaves* either opposite or alternate.

Section 1, consisting of plants whose flowers are borne on

a leafy stem, contains *Centunculus*, *Anagallis*, *Lyfimachia*, *Hottonia*, *Coris*, *Sheffieldia*, *Limofella*, *Tricentalis*, and *Arctia*.

Section 2, comprehends plants whose flower-stalks spring directly from the root, as well as the leaves, and are generally umbellate, with a many-leaved involucre; sometimes however they are simple and single-flowered. The genera are *Androsace*, *Primula*, *Cortusa*, *Soldanella*, *Dodecatheon*, and *Cyclamen*.

Jussieu subjoins a 3d Section, of plants akin to the *Lyfimachia*. These are *Gibbularia*, surely misplaced here; *Conoclea* of Aublet; *Tozzia*, which two last we should rather have referred to the order of *Pedicularis*; *Samolus*, *Utricularia*, *Pinguicula*, and *Mentyanthes*.

M. Ventenat has chosen to call this order *Primulaceæ*, and he is followed by Mr. Brown. The latter name is perhaps preferable, and there seems to be nothing fixed as yet amongst the students of natural orders, as to names or their terminations. The science is new and experimental at present, and rigid laws should not prevent improvements. It is far otherwise with names of genera and species, which are the current coin, not the paper currency, of the botanical realm.

LYSIMACHUS, in *Biography*, king of Thrace, one of the captains of Alexander the Great, rose from a very mean condition to the favour of that prince. At the partition of the empire of Alexander, in the year 323 B.C., Thrace, the Chersonese, and the countries adjacent to the Euxine, were allotted to Lyfimachus. When Antigonus had rendered himself formidable to all the other sharers, Lyfimachus joined in the league against him, with Seleucus, Ptolemy, and Cassander. By a subsequent treaty, Thrace was confirmed to him; and in imitation of other captains, he took the title of king. He founded the city of Lyfimachia in 309 B.C., and made it his capital. In conjunction with Seleucus, he gained the great battle of Ipsus. He afterwards seized upon Macedonia, having first expelled Pyrrhus from the throne; but his cruelty rendered him truly odious, and the murder of his son Agathocles so offended his subjects, that the most opulent and powerful revolted from him, and abandoned the kingdom. He pursued them into Asia, and declared war against Seleucus, who had given them a kind reception. He was killed in a bloody battle, in the 28th year B.C., and in the 80th of his age. His body was found in the heaps of slain by the fidelity of his dog, which had carefully watched near it. With great courage and abilities, he was characterized by a cruel and ferocious disposition, which rendered him unworthy of his high fortune. Justin mentions a curious fact concerning him, viz. that having offended Alexander, he was, as a punishment, thrown into the den of a furious lion; and when the ravenous animal darted upon him, he wrapped his hand in his mantle, and boldly thrust it into the lion's mouth, and by twisting his tongue, killed an adversary ready to devour him. This act of courage in self-defence recommended him to the monarch, who pardoned and took him into his favour. Univ. Hist.

LYSINE, in *Ancient Geography*, a town of Asia, in Pamphylia, between Comana and Cormasa, according to Ptolemy.

LYSINEMA, in *Botany*, from *λυσιν*, *separation*, and *μαζ*, *a thread or flamen*, because the flaments are unconnected with the corolla, proceeding from the receptacle, below the germen, by which character alone the genus is distinguished from *Eparis*, their habit being exactly the same. The tube of the corolla however is generally divided, more or less deeply, into five parts in *Lyfinema*. Brown Prodr.

Nov.

Nov. Holl. v. 1. 552.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Epacridae*, Brown.

Gen. Ch. Cal. Perianth inferior, of many erect, imbricated, coloured, permanent leaves; the inner ones gradually larger. Cor. of one petal, salver-shaped; its tube generally splitting into five parts; limb in five smooth beardless segments, obliquely twisted to the right. Nectary of five glands, surrounding the base of the germen. Stam. Filaments five, thread-shaped, equal, inserted into the receptacle; anthers incumbent, oblong, bursting lengthwise, rising just above the tube. Pist. Germen superior, roundish, with five furrows; style thread-shaped; stigma obtuse. Peric. Capsule of five cells and five valves. Seeds numerous, minute. Receptacles five, attached to the central column.

Eff. Ch. Calyx of many imbricated coloured leaves. Corolla salver-shaped; its limb five-cleft, beardless. Stamens inserted into the receptacle, the length of the tube. Capsule of five cells, with many seeds.

1. *L. pentapetalum*. Corolla divided to the bottom; its claws unconnected, longer than the calyx, externally smooth.—Found by Mr. Brown in the southern part of New Holland.

2. *L. ciliatum*. Corolla divided to the bottom; its claws cohering at the top, externally smooth, the length of the calyx.—Native of the same country. We have seen neither of these.

3. *L. lasianthum*. Corolla divided to the bottom; its claws externally woolly, rather longer than the calyx.—Gathered by Mr. Menzies at King George's Sound, on the south-west coast of New Holland. The stem is shrubby, as in all the rest, its branches very slender, smooth, round, leafy. Leaves scattered, about a quarter of an inch long, elliptic-oblong, narrow, obtuse, entire, smooth; flat above; convex beneath. Footstalks short, smooth. Flowers few, in a terminal simple spike, leaning one way, apparently tawny or bluish-coloured, each near half an inch long. Calyx-leaves blunt, with a membranous edge; the inner ones fringed. Petals obtuse.

4. *L. conspiciuum*. Tube of the corolla five-cleft above, longer than the calyx. Leaves lanceolate-awl-shaped, close-pressed.—Found by Mr. Brown in the south of New Holland.

5. *L. pungens*. (*Epacris pungens*; Cavan. Ic. v. 4. 26. t. 346.)—Tube of the corolla undivided, the length of the calyx. Leaves spreading, ovate, sharp-pointed.—Native of the country about Port Jackson, New South Wales, from whence specimens were sent in 1791 by Dr. White. The stem is woody, with many straight rigid branches, thickly beset with sessile, rigid, smooth, entire, ribbed, spinous, and taper-pointed leaves; their base ovate or heart-shaped, close-pressed, and partly clasping the stem; the rest spreading nearly horizontally, very pungent. Flowers white and fragrant, very elegant, in dense, leafy, terminal spikes. Segments of the corolla pointed, somewhat plaited when dry. Style prominent, hairy. We have already spoken of this shrub as *Epacris pungens*. (See *EPACRIS*.) Mr. Brown subjoins Dr. Sims's red-flowered plant, Curt. Mag. t. 1199, as a variety, and he adds that this *L. pungens* is an intermediate species, as it were, between *L. sinema* and *Epacris*. It agrees with the latter in its corolla, but has the insertion of the filaments proper to the former.

LYSIPPUS, in *Biography*, a celebrated sculptor and statuary, was born at Sicyon, and flourished in the time of Alexander the Great. He was originally a worker in brass, and then applied himself to painting, till his talents and inclination led him to fix on the profession of a sculptor. He worked with such extraordinary diligence and facility, that

he is said to have left 1500 performances, all of such excellence, that any one of them singly might have conferred celebrity on him as an artist. He attained to so high a reputation, that Alexander forbade any sculptor but Lysippus to make his statues. Lysippus improved the art of statuary by a better imitation of the hair, and by an attentive study of symmetry, in which he considered how the human figure appeared to the eye, not what were its exact proportions. The most admirable of his works were the statues of Alexander, of which he executed a series, beginning from his childhood; one of a man coming out of a bath, placed by Marcus Agrippa before his public baths; and being removed by Tiberius into his own chamber, the Roman people were so clamorous for its restitution, that the emperor thought it prudent to comply with their wishes. A chalet of the sun at Rhodes was one of his great works, which was, however, surpassed by a colossus at Tarentum 40 cubits high. His statue of Socrates, and those of the twenty-five horsemen who were drowned in the Granicus, were so highly valued, that, in the age of Augustus, they were sold for their weight in gold.

LYSIS, a Pythagorean philosopher, who flourished in the fifth century before Christ, was a native of Tarentum, who, according to Jamblichus, was instructed in his philosophy by Pythagoras himself. Being well initiated and excelling in the doctrines of his master, he opened a school for the purpose of instructing others, but would never admit persons of bad character among his auditors. He even refused, on that account, entrance to Cylon, one of the wealthiest people of the city. Cylon was exasperated at the neglect, as he thought it, and resolved on revenge. He caused the house of Milo, in which Lysis and forty other Pythagoreans were assembled, to be set on fire; meaning by the violence of a hired mob to assassinate those, by bludgeons or missile weapons, who should escape burning. Excepting Lysis and Archippus, they were every one burnt or floned to death. The philosopher now retired, first into Achaia, and afterward to Thebes, where he opened a school, and remained an useful instructor to the Grecian youth till he died. Among other famous disciples he could, it has been said, mention Epaminondas; though others seem to doubt the fact, and to be desirous of referring that honour to another person of the same name. Lysis is celebrated for having been a most exact and punctual performer of his promises, even on the most trivial occasions. He composed Commentaries on the philosophy of Pythagoras, which have not come down to our times. Some writers have attributed to him the "Golden Verses;" while others have given them to Philolaus, or Empedocles. There is still extant, under the name of Lysis, a letter addressed to Hipparchus, in which the latter is reproached for having divulged the secrets of the Pythagorean philosophy. It may be found in the "Opuscula Mythologica et Philosophica" of Dr. Thomas Gale.

LYSKO, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 52 miles S.W. of Novogrodek.

LYSOBYKI, a town of Poland, in the palatinate of Lublin; 20 miles N.N.W. of Lublin.

LYSSA, *Λυσσα*, a word used by medical authors to express that species of madness which is peculiar to dogs and wolves, but is communicated by their bite to man and other animals. Hence persons labouring under the dismal effects of such a bite, are called also *lyssodactyl*.

LYSENDORF, in *Geography*, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Prüm. The place contains 117, and the canton 1962 inhabitants, in 25 communes.

LYSTRA,

LYSTRA, a small town of America, in Nelson county, Kentucky, situated on a west water of Rolling Fork, a fourth branch of Salt river. N. lat. $37^{\circ} 25'$.

LYSWIK, a town of Sweden, in the province of Warmeland; 34 miles N. of Carlstadt.

LYTHRUM, in *Botany*, the *λυθρον* of Dioscorides, most probably received its name from the purple tinge of its flowers: *λυθρον* signifying *clotted*, or *gore blood*, to which substance this plant is similar in colour. Linn. Gen. 240. Schreb. 323. Willd. Sp. Pl. v. 2. 865. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 509. Art. Hort. Kew. ed. 2. v. 3. 149. Juss. 332. Lamarek Illustr. t. 408. Gertn. t. 62. (Salicaria; Tournef. t. 129.)—The *Cuphea* of Brown, in his history of Jamaica, united to *Lythrum* by Linnæus, is now by general consent separated, on account of its irregular flower, and capsule with a single cell.—Class and order, *Dodecandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Salicaria*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, cylindrical, striated, with twelve teeth, the alternate ones less. Cor. Petals six, oblong, rather obtuse, spreading, inserted into the base of the segments of the calyx. Stam. Filaments twelve, thread-shaped, the length of the calyx; the upper ones shorter than the lower; anthers simple, somewhat ascending. Pist. Germen superior, oblong; style awl-shaped, the length of the filaments, declining; stigma orbicular, ascending. Peric. Capsule oblong, pointed, covered by the calyx, of two cells. Seeds numerous, small.

Eff. Ch. Calyx inferior, with twelve teeth. Petals six, inserted into the calyx. Capsule with two cells and many seeds.

Obs. In some species of *Lythrum*, one-sixth of the parts of fructification is found to be deficient; in others only six filaments are to be seen.—We describe the following principal species as a sufficient illustration of the genus.

L. Salicaria. Purple Lythrum. Linn. Sp. Pl. 640. Engl. Bot. t. 1061. Curt. Lond. fasc. 3. t. 28.—Leaves opposite, lanceolate, heart-shaped at the base. Flowers spiked. Stamens twelve. A native of marshes and the banks of rivers, flowering in July and August.—Root perennial, woody, throwing up many stems. Stems three feet high, erect, wand-like, quadrangular (occasionally hexangular) leafy. Leaves opposite, sometimes, though rarely, three or four together, still more rarely alternate, sessile, smooth above, downy at the margin and underneath. Flowers in a whorled spike, purple.—One of our most showy wild plants, and extremely ornamental to the banks of ditches, ponds, and rivers, though occasionally to be met with in drier situations.

L. virgatum. Fine-branched Lythrum. Linn. Sp. Pl. 642. Jacq. Austr. t. 7. Curt. Mag. t. 1003.—Leaves opposite, lanceolate. Panicle straight. Flowers three together.—Originally found by Clusius in Austria, and in the isles of the Danube. It was introduced by Jacquin into the gardens at Kew in 1776, where it flowers from June to September.—Root perennial, thick. Stems upright; at the bottom, round, pale-brown mixed with green, generally leafless; towards the top square, leafy and branched. Leaves opposite, thickish, nearly sessile. Flowers six in a whorl, the lower ones more remote, all axillary, of a deep purple colour.—Linnæus notices a variety of *L. virgatum* which has fewer flowers in the whorl, and whose leaves are alternate.

L. hyssopifolium. Hyssop-leaved Lythrum, or Grafs-poly. Sm. Fl. Brit. 510. Engl. Bot. t. 292. (*L. Hyssopifolia*; Linn. Sp. Pl. 642. Jacq. Austr. t. 133.)—Leaves alternate, linear-lanceolate. Stamens six.—A rare English plant,

to be met with occasionally in moist places where water has stagnated through the winter. Common in many other parts of Europe, flowering in August.—Root annual, simple, attenuated. Stem a span high, branched at the base, erect. Leaves smooth, varying in breadth; the lower ones only, opposite. Flowers axillary, almost sessile, solitary, small, purple, hexandrous, though occasionally five-cleft and pentandrous.

LYTHRUM, in *Gardening*, contains a plant of the hardy, herbaceous, perennial kind, of which the species cultivated is the common or purple willow-herb (*L. Salicaria*.)

Method of Culture.—This sort and varieties may be readily increased by parting the roots in autumn, and planting them out in the situations where they are to remain. They may likewise be raised from seed sown at the same time, but the first is the readiest method. They delight in rather moist soil.

All of them are highly ornamental in the larger borders, clumps, and other parts of pleasure-grounds, being placed towards the back parts, from their full growth.

LYTTA, or LYTTA *Vesicatoria*, in the *Materia Medica*, the name given to the Blistering Fly.

The *Ceratum Lyttæ*, or *Ceratum Cantharidis* of P. L. 1787, is composed of spermaceti cerate, and blistering flies, in a very fine powder, in the proportion of six drachms of the former to a drachm of the latter, and is prepared by softening the cerate by heat, adding the flies, and mixing them together.

LYTTE, *Emplastrum*. See EMPLASTRUM.

LYTTÆ, *Tinctura*, *Tinctura Cantharidis*, P. L. 1787, tincture of blistering fly, is prepared by macerating for 14 days three drachms of blistering flies bruised, in two pints of proof spirit. In order that this preparation may be certain in its effects, it is necessary that the insects should be fresh and perfect: for want of attention to this circumstance, large doses have been given without any sensible effect. See BLISTER and CANTHARIDES.

LYTTA, in *Natural History*, a genus of insects, of which there are thirty-two species enumerated in Gmelin's edition of the Syst. Nat. The generic character is antennæ filiform; four unequal feelers, the hind ones clavate; thorax roundish; head inflexed gibbous; shells soft, flexible, as long as the abdomen. All the species of this genus are exotics, and scattered through the globe, as will be seen in the following enumeration: many of them reduced to powder are capable of vesicating the skin on application to the surface of the body.

Species.

VESICATORIA; Blister-fly. Green; antennæ black. This is the common *Cantharis vesicatoria*, or Spanish-fly of the shops: though the insect has been usually ranked under the genus *Meloe*, and has, indeed, been so referred to from the article BLISTER in our own work: it is found to have no claim as belonging to that genus, and we have accordingly restored it to its proper place. It inhabits many parts of Europe, on ash and elder trees. It is used for various purposes in pharmacy, but chiefly for raising blisters; it multiplies greatly, and has a nauseous smell. The odorous particles are extremely corrosive. The female insect, after impregnation, deposits her eggs in the ground, where they remain till they have undergone the various changes that are to bring forth the winged insects.

SEGETUM. Golden; shells green. This is a less species than the *Vesicatoria*; is found in Barbary among corn. The antennæ are black; head and thorax sometimes golden,

sometimes green with a gloss of gold; body golden; legs dusky.

NITIDULA. Green bronzed; shells testaceous; antennæ black. This species has been sometimes described as belonging to the English insects; but Gmelin describes it as inhabiting the Cape only.

COLLARIS. Black; crown, thorax, and legs ferruginous, the shells are of an azure colour. This is a large insect, and is found in the southern parts of Russia. The antennæ are ferruginous; edge of the thorax a little black. The male is as small again as the female.

GIGAS. Azure; breast ferruginous; it inhabits Guinea. The size of this insect is about the same as that of the *L. venicatoria*; one sex has the shells friate, but in the other they are smooth.

SYRIACA. Vilous, green-blue; thorax rounded and ferruginous. It inhabits the southern parts of Europe.

RUFICOLLIS. An inhabitant of the East Indies. Glabrous, green-gold; thorax rufous, tapering before.

TESTACEA. Above testaceous; shells with a large oblong black spot near the tip. It inhabits Tranquebar. The head is testaceous; mouth and antennæ black; thorax punctured and testaceous; shells smooth; body black.

FESTIVA. Shining brassy-green; shells testaceous with spots of brassy-green. The body is entirely green bronze; spot on the shells varying. Inhabits Siberia.

MARGINATA. Black; margins of the shells pale cinereous; inhabits the Cape of Good Hope; above opaque, beneath cinereous.

VITTATA. Shells black, with a yellow margin; an inhabitant of America. By some entomologists this is described as the *Cantharis vittata*. Head yellowish; crown with two black spots; thorax black, with three yellow lines; abdomen and legs black.

ATRATA. Body black, immaculate; inhabits Barbary, and is the *Meloe pennsylvanica* of some writers. About half the size of the *Vittata*, and entirely of a deep black.

ERYTHROCEPHALA. Black; head testaceous; thorax and shells with cinereous lines. This species is found in several parts of Austria; the head is testaceous, with a black line down the middle; mouth black; thorax channelled.

OCULATA. Black, with a yellow callous dot behind the eyes; inhabits Guinea. Body entirely black immaculate; behind the eyes on each side is a large raised yellow dot. Female apterous, shells abbreviated.

DURIA. Black; crown fulvous; thorax and shells immaculate. Inhabits Siberia; and is the *Meloe alpinicus* of some entomologists.

ASRA. Black; thorax rufous; this species is found in Africa; and is the *Cantharis asra* of Olivier.

HEMORRHODALIS. Blackish blue; end of the abdomen rufous; the antennæ are black; head and thorax vilous; body smooth.

QUADRIMACULATA. Black, glabrous; breast downy; shells yellowish-grey, with two black and almost square spots. A native of the northern parts of Asia; is found among flowers; and it exudes a very pleasant smelling oil from its legs. This is a circumstance attending likewise to the

FENESTRATA, which is glabrous, pale testaceous; thorax depressed; shells grey tipped with black, have two squarish yellow spots; found also in the Asiatic parts of Siberia, chiefly among flowers.

CLEMATIDIS. Black, with a steel-blue gloss; shell pale testaceous immaculate; found on the clematis in Siberia.

URALENSIS. Black, opaque, glabrous; this is often con-

founded with the *Atrata* above described, and is not sufficiently distinct from it. An inhabitant of Siberia.

SINICA. Black, opaque, glabrous; shells edged with white; head red; eyes, mouth and antennæ black. Is found on the lotus in divers parts of Sibiria. The joints of the antennæ, in the male, compressed and armed with a tooth.

LOBATA. Black, woolly; shells ventriferæ, fulvous, spotted, pale yellow with six black dots. Inhabits Siberia.

OMBLATA. Black, woolly; legs testaceous; thorax rufous, and shell yellowish, the latter with six obsolete black spots in the middle. Inhabits the Caspian sea, and has been described particularly by Pallas. Like the "*Punctipennis*" and "*Punctifrons*" it exudes an agreeable oil from its legs.

PECTINATA. Antennæ pectinate; body black; front red. It inhabits Siberia.

CINNABARINA. Black; thorax above, shells, and head on each side red. Inhabits Carniola.

RUBA. Black; head rufous. Inhabits Carniola.

SUBVILLOSA. Yellowish subvilous; antennæ tapering. Is found in many parts of France.

BICOLOR. Testaceous; shells tipped with black. Inhabits France.

FORMICARIA. Brown; the fore-part of the elytra, and the thorax, which is elongated, are red. This is found in France and other parts of Europe.

PUBESCENS. Black; head and thorax pubescent; shells yellow, with a ferruginous spot on each side behind; this insect has been found only in museums by modern naturalists.

FERRUGINEA. Ferruginous; head and thorax rufous; shells brown testaceous at the base. Inhabits various parts of Europe.

LYTTELTON, GEORGE, Lord, in *Biography*, was the eldest son of Sir Thomas Lyttelton, bart. of Hagley, in Worcestershire, where he was born in January 1708-9. He was educated at Eton, from which place he was removed to Christ-church college, Oxford. He was from an early age distinguished for his proficiency in classical learning, and some of his poems were the fruit of his youthful studies. When he had completed his course at Oxford, he set out upon a tour to the continent, and his letters to his father during his absence are replete with remarks displaying solid judgment and sound principles, while, at the same time, they afford a most pleasing example of filial affection and duty, joined with the unreserved confidence of intimate friendship. During his residence abroad, he wrote a poetical epistle to Dr. Aylough, which is thought to be one of the best of his works, and another to Pope, elegantly complimentary of that great poet. Upon his return from the continent, he was chosen representative, in parliament, for the borough of Oakhampton. At this time his father was a supporter of the existing ministry under Walpole. The son, animated with that patriotic ardour, which scarcely ever fails to inspire the bosom of virtuous and liberal youth, and which it is almost incredible for a young man not to feel, took a contrary part, and distinguished himself among the opposers of administration. His name is to be found among those of the minority in almost every important debate, and he zealously concurred in every measure adopted by Pultney, Pitt, and other leaders of that party. In 1735 he published his "*Persian Letters*," of which it appears, by the testimony of Dr. Warton, he was rather ashamed at the close of life. Mr. Lyttelton obtained the notice and friendship of Frederic prince of Wales, and was appointed secretary to his royal highness; by his instigation it is imagined the prince assumed

the patronage of letters, the beneficial effect of which Mallet, Thomson, and others experienced. It was probably on this account that Pope gave him the praise of pure patriotism, rather than from any regard to his political principles :

“Free as young Lyttelton her cause pursue ;
Still true to virtue, and as warm as true.”

On the death of Thomson, who left his affairs in a very embarrassed condition, Mr. Lyttelton took that poet's sister under his protection. He revised the tragedy of *Coriolanus*, and brought it out at the theatre-royal Covent-garden, with a prologue of his own writing, in which he so affectingly lamented the loss of that bard, that not only Quin, who spoke the lines, but the whole audience, spontaneously burst into tears. He had married, in 1742, Lucy, daughter of Hugh Fortescue, esq. and enjoyed in her society the most unalloyed happiness, which was miserably interrupted by her death in 1746, leaving him one son, Thomas, the late lord, and a daughter, Lucy, who married lord Valentia. On the monument of his beloved lady, he inscribed the following lines.

“Made to engage all hearts, and charm all eyes :
Tho' meek, magnanimous ; tho' witty, wife ;
Polite, as all her life in courts had been ;
Yet good, as she the world had never seen :
The noble fire of an exalted mind,
With gentlest female tenderness combin'd.
Her speech was the melodious voice of love
Her song the warbling of the vernal grove.
Her eloquence was sweeter than her song,
Soft as her heart, and as her reason strong.
Her form each beauty of her mind express'd
Her mind was virtue by the Graces dress'd.”

Besides these lines, her affectionate husband wrote a monody on her death, which displays much natural feeling amidst the more elaborate strains of a poet's imagination.

On the expulsion of Walpole from the ministry, Lyttelton, in 1744, was appointed one of the lords of the treasury. He was always assiduous in his parliamentary attendance, and a vigorous supporter of the measures in which he partook, but never attained the station of leader. He spoke with ease and fluency, but was not eloquent in the usual sense of the word. In early life, he seems to have entertained strong doubts of the truth of revelation, probably from the corruptions of it, which he had witnessed on the continent, but upon serious and impartial inquiry he became a firm believer in Christianity, and wrote in its defence, “*A Dissertation on the Conversion of St. Paul*,” which has ever been regarded as a masterly performance. This piece was written at the desire of Gilbert West, esq. in consequence of Mr. Lyttelton's asserting, that, besides all proofs of the Christian religion, which might be drawn from the prophecies of the Old Testament, from the necessary connection it has with the whole system of the Jewish religion, from the miracles of Christ, and from the evidence of his resurrection by all the other apostles, he thought the conversion of St. Paul alone, was of itself a demonstration sufficient to prove Christianity to be a divine revelation.

In 1749 he married again, but the conduct of his second

wife proved so little to his satisfaction, that a separation by mutual consent ensued in a very short time. By the death of his father in 1751, he succeeded to the title and estate. His taste for rural ornament he displayed at Hagley, which he rendered one of the most delightful places in the kingdom. He occupied several posts under government, but at the dissolution of the ministry in 1759 he went out of office, and was, as a reward for his services, raised to the honour of a peerage, under the style and title of baron Lyttelton, of Frankley, in the county of Worcester.

From this period he chiefly devoted himself to the pursuits of literature, and to an extensive correspondence with the pious and learned. In 1760 he published “*Dialogues of the Dead*,” a work abounding in good sense and sound morality, and which was well received by the public. In 1767 and 1771 he gave the world his “*History of Henry II.*,” in three vols. 4to. a valuable work, which had occupied a great portion of the latter part of his life, and on which he probably placed his chief expectations for future fame. He has given an accurate and comprehensive view of the English constitution, as it existed at the early period of our history with which his book is concerned, and of the changes subsequent to the Norman conquest. The style of the history is good ; its sentiments are judicious and liberal, favourable to the best interests of mankind. The poems of this nobleman preserve a place among the select productions of the British muse, rather on account of the correctness of their versification, the elegance of their diction, and the delicacy of their sentiments, than as exhibiting any uncommon poetical powers. As a politician, his speeches on the Scotch and mutiny bills, in 1747 ; on the naturalization of the Jews in 1753 ; and on the privilege of parliament in 1763, hold him out to public estimation. He died in August 1773, in the 64th year of his age. His miscellaneous works were published after his death in one volume 4to. His lordship, among other qualities, had a remarkable facility of striking out an extemporary compliment, which obtained for him a considerable share of reputation ; an instance is recorded, when lord Cobham, in a large company, mentioned his design of putting up a bust of lady Suffolk in his beautiful gardens at Stowe, he turned to his friend Lyttelton and said “*George, you must furnish me with a motto for it.*” I will, said he, and instantly produced the couplet ;

“Her wit and beauty for a court were made,
But truth and goodness fit her for a shade.”

Johnson's *Lives of the Poets*.

LYTTLETON, CHARLES, an English prelate, brother of the above, was educated at Eton in grammar learning, from whence he entered himself at University college, Oxford, and afterwards studied the law in the Temple and was called to the bar. He, however, soon quitted the profession, entered into holy orders, and in 1747 was appointed chaplain to the king. The year following he was made dean of Exeter, and in 1762 promoted to the bishopric of Carlisle. He was several years president of the Society of Antiquaries, and contributed several articles to their Transactions. He died in 1768.

M.

M A A

M, A liquid consonant, and the twelfth letter in the alphabet.

It has one unvaried sound, and is pronounced by striking the upper lip against the lower; in which the pronunciation of this letter agrees with that of *b*; the only difference between the two consisting in a little motion made in the nose in pronouncing *M*, and not in *b*: whence it happens, that those who have taken cold, for *M* ordinarily pronounce *b*; the nose, in that case, being disabled from making the necessary motion.

All consonants are formed with the aid of vowels; in *em* the vowel precedes, in *be* it follows: and *M* is never mute.

Quintilian observes, that the *M* sometimes ends Latin words, but never Greek ones; the Greeks always changing it in that case into *n*, for the sake of the better sound.

M is also a numeral letter, and among the ancients was used for a thousand; according to the verse,

“*M* caput est numeri, quem scimus mille teneri.”

When a dash is added at the top of it, as \overline{M} ; it signifies a thousand times a thousand.

M, as an abbreviation, stands for *Manlius*, *Marcus*, *Martius*, and *Mucius*: *M.A.* signifies *magister artium*, or master of arts; *MS.* manuscript, and *MSS.* manuscripts.

M, in *Astronomical Tables*, and other things of that kind, is used for *Meridional*, or southern; and sometimes for *Meridian*, or mid-day.

M, in *Medicinal Prescription*, is frequently used to signify a maniple, or handful: and it is sometimes also put at the end of a recipe, for *misce*, *mingle*; or for *mixtura*, a *mixture*. Thus, *m. f. julapium*, signifies *mix*, and *make a julep*.

M, in *Law*, the brand or stigma of a person convicted of man-slaughter, and admitted to the benefit of his clergy.

It is to be burnt on the brawn of his left thumb.

M, in *Music*. This letter in old psalm-tunes, harmonized, stands for *mean*, or middle part, the second treble, and sometimes the counter-tenor. In Scarlatti's lessons composed in Spain, it implies *mano manca*, or left hand.

MA, in *Hindoo Mythology*, is a name of Parvati, the consort of Siva, as noticed under those articles.

MAA, in *Geography*, a town of Hindoostan, in Dowlatabad; five miles N.E. of Beder.

MAAB, a settlement of West Greenland. N. lat. 62° 6'. W. long. 48° 30'.

MAACAH, *MACAATH*, or *Beth-Maacha*, in *Ancient Geography*, a little province of Syria, E. and N. of the sources of Jordan, toward Damascus. We learn from Joshua (xiii. 13.) that the Israelites would not destroy the Maachathites, but permitted them to dwell in the land; and from Deut. iii. 14. and Josh. xii. 5, that the lot of the half tribe of Manasseh beyond Jordan extended to the country.

M A A

Hence the small canton, near the head of Jordan, on the E. side of it, in the way to Damascus, was called Maachonitis, or Machonitis.

MAADEN AL NOCRA, in *Geography*, a town of Arabia Felix, in the province of Hedjas; 140 miles E. of Hagiaz.

MAADEN Uzzumurud, the *Mine of Emeralds*, a mountain of Egypt, on the coast of the Red sea; 90 miles S. of Cosseir.

MAADIE', denoting *Passage*, is the name of a village consisting of two or three houses, upon the E. bank of the Nile, so called because they stand at the place facing the usual *passage* to the Delta. Dr. Shaw conceived this to be the site of the ancient Heraclea, but Sonnini made diligent examination on this spot, and could perceive no vestiges of buildings of a remote time, but half a league further, he remarked upon the coast old walls and ruins, which may be traced a long way into the sea, and which are probably the remains of Heraclea or Heracleum. Maadié is distant about six leagues from Alexandria, on a lake of the same name, which is the extremity of the Canopic branch of the Nile. The lake communicates with the Mediterranean by a narrow opening, at which the French raised a block-house, from which they were driven by the British, under lieut. Brown. Maadié is five miles E. of Aboukir.

MAAGRUNNI, two islands on the E. side of the gulf of Bothnia. N. lat. 65° 25'. E. long. 24° 56'.

MAALMORIE, a cape of Scotland, on the S.E. part of the island of Ha.

MAALUM, a town of Bengal; eight miles E. of Toree.

MAAN, JOHN, in *Biography*, a French ecclesiastical historian, was born at Tours, where he probably received the elements of a learned education, being designed for the ecclesiastical profession: in due time he was admitted doctor by the faculty of the Sorbonne, and became canon and precentor of the church of Tours. He zealously devoted his talents and learning to the service of that religion in which he had been brought up. In 1667 he printed at his own house a work entitled “*Sancta et Metropolitana Ecclesia Turonensis, Sacrorum Pontificum suorum orata virtutibus, et sanctissimis Conciliorum Institutis decorata.*” This work is highly esteemed by the French, who represent it as replete with erudition and curious researches, and as reflecting high honour on the church of Tours and its author. Moreri.

MAANA, in *Geography*, a town of Africa, in the kingdom of Kajanga, the residence of the king, bordering on a branch of the river Senegal, and within a short distance of the ruins of Fort St. Joseph.

MAANINGA, a town of Sweden, in the government of Kuopio; 20 miles N.N.W. of Kuopio

MAAR, a small island in the East Indian sea, near the South coast of the island of Ceram. S. lat. 3° 30'. E. long. 13° 25'.

MAARABAI, a harbour on the W. coast of the island of Ulitea, in the South Pacific ocean. S. lat. 16° 53'. W. long. 151° 27'.

MAARRA, a town of Asiatic Turkey, in the government of Aleppo; the residence of an aga; 45 miles S.S.E. of Aleppo.

MAAS DRUK, in *Biography*, a painter, born at Haerlem in 1656. He at first painted still life, after that he studied with and imitated Berchem, but is best known by pictures of battles, processions, and cavalcades of horses, somewhat in the style of Vander Meulen, though not wrought so free as the works of that artist.

There were two other painters of this name, Arnold van Maas, a disciple of Teniers, who died young, and Nicholas Maas, who was born at Dort in 1632, and was educated in the school of Rembrandt. He practised portrait painting with considerable success. He lived to the age of 61, and died in 1693.

MAASEYCK, in *Geography*, a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Ruremonde. The place contains 2205, and the canton 14,704 inhabitants, on a territory of 2574 kilometres, in 13 communes.

MAASIN, a town on the W. coast of the island of Leyta. N. lat. 10° 12'. E. long. 124° 49'.

MAASS, in *Commerce*. See MAAS.

MAAT, a superficial measure of land in Holland, containing 500 square rutes, of which 600 are equal to a morgen or acre. A single square rute contains 169 square feet, each foot being = 121 square inches = 124 English inches.

MAATTAN, in *Geography*, a town of Hindoostan, in Bahar; 34 miles N.N.E. of Durbunga.

MAATZ, NICHOLAS, in *Biography*, an eminent German organ-builder in the sixteenth century, celebrated by Praetorius, and in Werckmeister's organ-grunning, rediv. In 1543 he erected an organ at Stralsund with 43 stops, and afterwards was engaged in the service of the king of Denmark.

MAB. See MOAB.

MABA, in *Botany*, is the vernacular name of this genus amongst the islanders of the South Seas. It was first described by Forster, and afterwards taken up by Linnaeus, Schreber, and other authors. Forst. Gen. 61. Linn. Suppl. 65. Schreb. 1758. Mart. Mill. Dict. v. 3. Juss. 418. Lamarck Illustr. t. 83.—Class and order, *Diccia Triandra*. Nat. Ord. uncertain.

Gen. Ch. Male. Cal. Perianth inferior, cloven half way down into three acute, villous segments. Cor. of one petal, tubular, hairy on the outside; tube cylindrical, longer than the calyx; limb in three, ovate, thickish, erect divisions. Stam. Filaments three, thread-shaped, shorter than the calyx; anthers erect, ovate. Pist. Rudiment globose, nearly sessile in the middle of the flower.—Female. Cal. Perianth inferior, permanent as in the male. Cor. and Pist. unknown. Peric. Deupa superior, ovate-oblong, of two cells, each containing two oblong, triangular seeds or nuts, somewhat convex at their base, flat on each side.

Eff. Ch. Male. Calyx three-lobed. Corolla externally hairy. Pist. three-lobed. Female. Calyx as in the male. Deupa superior, of two cells.

1. M. *Spila*. Forst. Gen. t. 61. Linn. Syst. Veg. ed. 14. 881. Suppl. 426.—A native of the Friendly Islands, more particularly of Tonga Tabu and Namoka.—This is a *shrub* whose general herbage is extremely smooth,

its young shoots and early leaves alone being hairy. *Leaves* alternate, on short footstalks, elliptical, veined, very smooth. *Stalks* axillary, short, mostly three-flowered. *Flowers* small, and curious as Linnaeus remarks for having the outside of the calyx and corolla extremely hairy.

Forster, in his work on esculent plants, p. 54, mentions another species, or variety, of this genus, which he calls *Maba major*; the fruit of which is three times as big as that of *elliptica*, the kernels tough and insipid. The same author says that the natives eat the nuts of it, and that they were offered for sale to our people.

MABANOWEA, in *Geography*, a town of Poland, in Volhynia; 12 miles S. of Berdyczow.

MABBY, a kind of wine made from potatoes. It is said to be used in Barbadoes.

MABEA, in *Botany*, is derived from the Caribbee name of this plant, *Piriri Mabé*. Aublet first described the genus in his *Plante Guianeses*, and says it is called *Bois à Calumet* by the French, because the negroes use its smaller branches as pipes for smoking. Aubl. Guian. 867. Schreb. 641. Willd. Sp. Pl. v. 4. 404. Mart. Mill. Dict. v. 3. Juss. 388. Lamarck Illustr. t. 773.—Class and order, *Monacia Polyantha*. Nat. Ord. *Tricocco*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male. Cal. Perianth inferior, of one leaf, five-toothed, acute. Cor. none. Stam. Filaments from nine to twelve, inserted into the bottom of the calyx; anthers roundish.—Female. Cal. Perianth of one leaf, erect, five-toothed, acute. Cor. none. Pist. Germen superior, oblong, somewhat triangular, longer than the calyx; style long; stigma three, thread-shaped, revolute. Peric. Capsule enclosed in a thick coat, roundish, of three lobes and three cell, each cell two-valved, bursting with elasticity. Seeds solitary, roundish, reddish, variegated with grey spots.

Eff. Ch. Male. Calyx five-toothed. Corolla none. Stamens from nine to twelve inserted into the calyx.—Female. Calyx five-toothed. Corolla none. Stigmas three. Capsule three-lobed, of three cells. Seeds solitary.

Obs. Jussieu remarks that in the description of the female flowers of *Maba* instead of "a single style," it should rather be "styles three, closely united or glued into one."

1. M. *Piriri*. Aubl. Guian. t. 334. f. 1.—Leaves ovate-oblong, attenuated at the base, pointed.—Found in Guiana and Cayenne, where it flowered and bore fruit in May.—The *trunk* of this plant rises to about five feet in height, and puts forth numerous, twiggly *branches* very long, spreading and entangling themselves among the neighbouring trees, covered with an ash-coloured *lark*. *Leaves* alternate, on short footstalks, entire, green above, whitish beneath. *Stipules* two, long, narrow, deciduous. *Flowers* copious, in long panicles; the males three on a common stalk, with two glands and a bractea at the base: female flowers beneath the male, solitary. Every part of the plant when wounded abounds with a milky secretion.

2. M. *Tapari*. Aubl. Guian. t. 334. f. 2.—Leaves oblong, rounded at each end, pointed, somewhat heart-shaped at the base.—Native of Guiana, flowering with the last. This *shrub* differs from the last in having the *bark* of its trunk and branches of a reddish colour. The *leaves* are larger, less elongated, and terminated by a short point, curiously veined with red underneath. The *fruit* is also larger, but in other respects it entirely accords with the preceding.

MABER, in *Geography*, a town of Persia, in Chusilan; 48 miles S.S.W. of Satter.

MABERIA, a lake of Africa, in the country of *Nigala*, which see; the same with the lake of Dibbi; formed by

by the river Joliba, which runs to the *ea*, but mistaken by d'Anville and Delisle for the head of the river Senegal, which runs to the *sw*.

MABEUSE, or MABEUGE, JOHN DL, in *Biography*, one of the early laborious practitioners in the art of painting after the use of oil became known in Flanders. He was born at Maubeuge, in Hainault, in 1499.

He was invited by Henry VIII. to England, and employed by him to paint the portraits of his children. By his neat mode of finishing, and the smoothness and high polish of his works, he gained in this country, where the art of painting was then almost unknown, a very considerable reputation, and in consequence his paintings are not unfrequent among us.

They are known by their dry, stiff, and formal manner; both of action in the figures and in the foldings of their draperies, by a total lack of chiaro-scuro, and yet possessing much ingenious taste in colour: great care in the faces, which always appear to have been portraits; and an almost boundless labour in the finishing; particularly of all the ornamental parts, such as gems, pearls, &c. &c. which he was fond of bestowing lavishly.

He is said to have been immoderately addicted to drinking, though he lived to the age of 63.

MABILLON, JOHN, a very learned French Benedictine monk, was born at Pierre-mont, a village belonging to the diocese of Rheims, in the year 1632. He was instructed in grammar learning by one of his uncles, who afterwards sent him to the college of Rheims, where he soon distinguished himself by the vivacity of his genius, and an uncommon application to study. Hence he was taken into the seminary of the cathedral, in which the young persons designed for the service of the diocese were educated. He continued here three years, and took the habit in an abbey belonging to the Benedictines of the congregation of St. Maur in 1653, and in the following year he made his profession. The highest expectations were formed of him; but an incessant and almost perpetual head-ache rendered him incapable of application, and he was sent to different places in the country for the recovery of his health. In the year 1660 he was ordained priest at Amiens, and as he still laboured under so much indisposition, as to render it unfit for him to apply to his studies, he was accordingly employed in such temporal affairs of the congregation as were more adapted to his enfeebled constitution. In 1663, in order to restrain him from close studies, he was sent to St. Dennis, and was employed in the low office of exhibiting to strangers the various treasures and ancient monuments of the abbey. The duties of this servile post were ill adapted to his mind, and an accident which occurred shortly relieved him from the burden which was become almost intolerable. He broke a mirror, which it was pretended belonged to the pret Virgin; this so enraged his superiors, that they gladly allowed him to make his retreat. His vacant hours he employed in reading the fathers, and in laying up large stores of theological, ecclesiastical, and critical learning. In 1764 he went to Paris to assist d'Achery in compiling his *"Spicilegium,"* and took a large share in the business. The zeal and talents which he manifested in this work caused him to be appointed to superintend the publication of a complete edition of the works of St. Bernard, which he executed with much correctness, judgment, and learning. This work was published, in 1767, in two folio volumes, and also in nine volumes octavo. Immediately after the publication of this great work, he was employed in completing the lives of the saints, for which d'Achery and Chantouin had been

collecting and digesting materials. The first volume was published in 1668, under the title of *"Acta Sanctorum Ordinis S. Benedicti, &c."* this was followed at different periods by eight others, of which the last was published in 1702. The work was regarded by the journals of the day, "not as a simple collection of records relating to monastic history, but as a valuable compilation of ancient monuments, which being illustrated by learned notes, threw much light on the most obscure part of ecclesiastical history. The prefaces themselves would secure to the author an immortal reputation. The manners and usages of those dark ages are examined with great care, and an hundred important questions are discussed by an exact and solid critique." The prefaces were reckoned so valuable, that they were published separately in 1732, in quarto. In 1674 he published *"De Pane Eucharistico azimo et fermentato Dissertatio,"* intended to prove that the Latin church made use of leavened bread in the consecration of the Eucharist for many ages, and that the use of unleavened bread was not introduced till after Pharisæus's schism. In the following year he published *"Vetus Analactorum, &c."* but the work which has done most honour to the memory of Mabillon appeared in 1681, entitled *"De Re Diplomatica Libri sex, &c."* So high was the opinion generally entertained of his extraordinary merit, that the celebrated Colbert was desirous of bestowing on him a pension of two thousand livres, but his unambitious and disinterested spirit led him to decline that generous offer. In 1682, Colbert engaged him to take a journey into Brandenburg, for the purpose of examining some ancient titles relating to the royal family; after which he sent him into Germany, to search into the archives and libraries of the ancient abbies in that country, for such documents as might contribute to illustrate the history of France, and that of the church in general, and of the church of France in particular. The results of his enquiries into these subjects were given in the fourth volume of his *"Analactorum."* In 1685, he published *"De Liturgia Gallicana Libri tres, in quibus veteris ritus, quæ ante annos mille apud Gallos in usu erat, forma ritusque erantur ex antiquis monumentis, &c."* In the same year Mabillon was sent at the king's expence into Italy, with the same view as he had been formerly sent into Germany, and was received at Rome with great respect; he had free access granted him to all the archive, and to all the libraries, from which he collected a vast number of interesting and important papers, adapted to the design of his journey. On his return to France he carried with him a fine collection of books and rare MSS. which he placed in his majesty's library; and in 1687 he published an account of his journey, and of the pieces which he had discovered, under the title of *"Museum Italicum, seu Collectio veterum Scriptorum ex Bibliothecis Italicis eruta, &c."* in two volumes 4to. In 1688, father Mabillon engaged in a dispute between the Benedictines of Burgundy, and the canons regular, on the subject of the precedence of those orders in the choir, and, in 1701, he entered into a controversy with father Rance, abbot of La Trappe, who maintained, that learning and the sciences were foreign to the monastic profession, and who had prohibited the monks almost all sorts of reading excepting that of the scriptures and certain moral treatises. In 1695 he published a work, which involved him in much controversy and a very serious difficulties, entitled *"Eusebii Romani ad Theophilum Galum Epistolæ de Cultu sanctorum Ignotorum."* It was received by the superstitious and interested, particularly at Rome, in a most unfavourable manner. For some time it was attacked only by complaints, murmurs, and criticisms published

published in Germany, France, and Italy; but in 1701 it was brought before the congregation of the *Index*, by whom the author would unquestionably have been censured, if he had not agreed to reprint it with such alterations, emendations, and omissions as should be suggested to him. In the same year Mabillon was chosen honorary member of the Academy of Inscriptions, and published the first volume of the last great work to which he devoted his labours, entitled "*Annales Ordinis S. Benedicti in quibus non modo res Monasticæ, sed etiam Ecclesiasticæ Historiæ non minima pars continetur.*" The second, third, and fourth volumes succeeded, and the fifth was composed by Mabillon, but not published till after his decease. Mabillon died in December 1707, soon after he had completed his seventy-fifth year. In speaking of his great merit, Dupin says, "The voice of the public, and the general esteem of all the learned, are a much better commendation of him than any thing which we can say. His profound learning appears from his works; his modesty, humility, meekness, and piety, are no less known to those who have had the least conversation with him. His style is masculine, pure, clear, and methodical, without affectation or superfluous ornaments, and suitable to the subjects of which he has treated." In 1724 the posthumous works of our author were published in three volumes 4to. by Thuillier. Moreri. Dupin.

MABLY, BENNET DE, abbé, an eminent political writer, was born at Grenoble in 1709. He was brother of the abbé Condillac, whom he resembled in acuteness and penetration. He devoted himself to the study of literature, and died at Paris in 1785. His principal works are "Observations on the Greeks;" "Observations on the Romans;" "Parallel of the Romans and French;" "Observations on the History of France;" "Discourses on History." All the writings of this author display deep thinking, sound moral principles, and a great regard for the good of mankind. He is, however, thought to be too much of a panegyrist of the ancients, and too fond of applying their political maxims to the very different circumstances of modern states. The work of his old age, entitled "*Sur les Constitutions des Etats Unis de l'Amerique,*" gave offence by some sentiments adverse to civil liberty and religious toleration.

MABOUJAS, the *Devil-lizard*, in *Zoology*, a species of American lizard, so called from its ugliness and disagreeable aspect. It grows to six or seven inches long, and to the thickness of a thumb, and is found in the trunks of rotten trees, and in marshy places, where the sun-beams seldom reach; it is all over of a glossy black colour, and looks as if smeared over with oil.

MABOUL, JAMES, in *Biography*, an eminent French prelate, distinguished for his pulpit eloquence, and particularly for his orations delivered in praise of deceased persons of merit, was descended from a family of high rank. He obtained considerable eminence in the church, and was employed by the duke of Orleans, the regent, in a fruitless attempt to reconcile the hostile parties who were contending about the bull *Unigenitus*. His funeral discourses were published in one volume 12mo. in 1749: they are said to be distinguished by that sweetness of style, that nobleness of sentiment, that elevation, that unction, and that touching simplicity, which are the characteristics of a good mind, and of true genius. Moreri.

MABRA, in *Geography*, a town of Algiers, in the gulf of Bona; 10 miles W. of Bona.

MAC, an Irish word signifying *son*; frequently prefixed to surnames; as *Macdonald*, for Donald's son; *MacLaurin*, for Laurence's son, &c.

MACA, in *Geography*, a town of Africa, in Hoval; 20 miles from the mouth of the Senegal.

MACABALAR BAY, a bay on the N.W. coast of the island of Mindanao.

MACABRA, a town of Africa, in Sennaar; 40 miles S.S.W. of Meroe.

MACACO, in *Zoology*. See LEMUR *Macaco*.

MACADRA, in *Geography*, a town of Arabia, in Yemen; 32 miles S. of Chamir.

MACÆ, in *Ancient Geography*, a people of Africa, E. of the Nufamones and near the sea. Some have supposed they are the same with those called Syrtites by Ptolemy, because they inhabited towards the Great Syrtis. The Cinyps watered their country, and hence Silius Italicus denominates them Cinyphii Macæ.

MACAENS de Caminho, in *Geography*, a town of Portugal, in Estremadura; 33 miles S.S.E. of Coimbra.

MACAIRE, ST., a town of France, in the department of the Gironde, and chief place of a canton, in the district of La Reole. The place contains 1483, and the canton 9980 inhabitants, on a territory of 102½ kilometres, in 15 communes.

MACALLESTER'S BAY, a bay on the E. coast of the island of Mull. N. lat. 56° 30'. W. long. 5° 45'.

MACALUNGO, a town of Africa, in Mozambique. S. lat. 17°. E. long. 39°.

MACAM, *Indian apple*, in *Natural History*, the name of a common East Indian fruit: it is of a round shape, and about the size of our common wild crabs which grow in the hedges: instead of the several small seeds, which our crabs and apples contain, this fruit has only one hard kernel; it is of an acid taste, and of a raw and not very agreeable smell; the tree which produces this fruit does not grow to any height: it resembles the quince tree in its leaves, except that they have a yellowish cast. Mem. Acad. Par. 1699.

MACAN, in *Geography*, a town of Persia, in Khorasan; 60 miles W. of Meru-Shahighian.

MACANAO, a small island in the Caribbean sea, near the W. coast of Margarita. N. lat. 11°. W. long. 64° 40'.

MACANEA, in *Botany*, is a name adopted by Jussieu for the *Macabanea* of Aublet described in the supplement of his Plants of Guiana, and figured in t. 371 of that work. Neither of those authors had seen any of the parts of fructification except the *berry* and *seeds* which are thus described. *Peric.* Berry large, pear-shaped, of one cell, pulpy within; its outside leathery, sprinkled with red spots. *Seeds* from four to six, ovate, leathery, covered with a membrane and lying in a white pulp. Aublet, who found this plant in fruit in June, calls it by the specific name of *guianensis*, with the following description.—*Shrub* putting forth numerous *branches*, twisting themselves about the neighbouring trees. *Leaves* opposite, on footstalks, toothed, ovate, acute, smooth. *Fruit* axillary, in clusters.—From the imperfect state in which *Macanea* is known, we cannot pronounce to what class it belongs. Jussieu ranks it amongst the Natural Order of *Guttifera*, and says that it is nearly allied to *Mammea* and *Singana*.

MACANNA, in *Geography*, a kingdom of Africa, S. of Bambouk.

MACAO, a town of Portugal, in Estremadura; 12 miles N.E. of Abantes.

MACAO, a sea-port town of China, in the province of Quang-tong, situated at the mouth of the Tigris, in the entrance of the bay of Canton, and built on a peninsula, or rather a small island, because it is separated from the land by a river, where the ebbing and flowing of the sea are sensibly felt. This tongue of land is joined to the rest of the island only by a small neck, about 100 yards across. The Portuguese obtained this port from the emperor Camly, as a reward for the assistance they gave to the Chinese in destroying the pirates, who from the islands in the vicinity of Canton infested the seas and ravaged all the coasts of China. Some writers pretend, that this city had no inhabitants but pirates when the Portuguese formed an establishment in it; and that they were only permitted to build huts covered with straw. However this be, their whole extent of territory, bounded by a wall, is not more than eight miles in circumference. In this small spot, the Portuguese carried on, for a long time, almost exclusively, a considerable traffic with the Chinese empire, and with other countries in Asia, particularly Japan, Tonquin, Cochin-China, and Siam. But by the luxury occasioned by increase of wealth and the injurious oppression of the Chinese, the enterprising spirit of the Portuguese declined, and the inhabitants of Macao became enervated by a tropical climate. Their trade to Japan failed; their other speculations became precarious; and this once prosperous settlement is now very much reduced. The houses at Macao are built after the European manner, but they are low, and make little show. Here are 13 churches and chapels, and 50 priests, to minister to the devotion of between four and five thousand laity. Of the two pagan temples at Macao, belonging to the Chinese, one is curiously situated among a confused heap of immense masses of granite. This temple is comprised of three separate buildings one over the other; the only approach to which is by a winding flight of steps hewn out of the solid rock. The cave of Camoens, situated a little above the loftiest eminence in the town, was constructed, probably, in the same manner as the temple above described, by bringing together a vast number of rocks. This cave, from a tradition current in the settlement, belonged to Camoens, a Portuguese poet, who resided a considerable time at Macao, and in which cave, it is said, he wrote the celebrated poem of the *Lusiad*. The whole population of Macao, according to the statement of La Perouse, may be computed at 20,000, of whom 100 are Portuguese by birth, 2000 metis, or half Indians and half Portuguese, with as many Caffre slaves, their domestics. The rest are Chinese, who employ themselves in commerce and different trades, by which they lay the Portuguese under contribution to their industry. These last, though almost all Mulattoes, would think themselves disgraced, if they supported their families by exercising any mechanic art, though their pride is not above continually soliciting charity, with importunity, from every one that passes by them.

The road-head of Macao is sufficiently spacious to contain 60 gun-ships at the entrance of Typa; and in its harbour, which is below the town, and communicates with the river up to the eastward, ships of seven or eight hundred tons, with half their lading. The mouth of this harbour is defended by a fortress of two batteries, which must be kept within pistol-shot in entering. Three small forts, two of which are mounted with twelve guns, and the third with six, protect the south side of the town from every attempt of the Chinese. These fortifications, which are in the worst possible state, would be far from formidable to Europeans, but they may easily overawe all the maritime forces of the

Chinese. A mountain also commands the road, where a detachment of troops could hold out a very long siege. The Portuguese of Macao, more devout than warlike, have built a church on the ruins of a fort, which covered this mountain, forming, at that time, an impregnable post. The side next the land is defended by two fortresses, one of which is mounted with 40 guns, and capable of containing a garrison of 1000 men. It is provided with a cistern, two springs of running water, and casemates for laying up warlike ammunition and provisions. The other, which mounts 30 guns, cannot receive above 300 men, and has a very abundant spring that never fails. These two citadels command the whole country. The Portuguese frontiers extend nearly a league from the town, and are bounded by a wall guarded by a mandarin and a few soldiers. This mandarin is the true governor of Macao, whom all the Chinese obey, though he is not allowed to sleep within these limits. But he may examine all the fortifications, inspect the custom-houses, &c.; and on these occasions the Portuguese are obliged to give him a salute of five guns: but no European can make a single step on the Chinese territory, beyond the wall, which would subject him either to imprisonment or a heavy contribution. The palace of the Chinese mandarin is in the middle of the city; and the Portuguese are constrained to pay a tribute of 100,000 ducats for the liberty of choosing their own magistrates, exercising their religion, and living according to their own laws. The viceroy of Goa nominates to all civil and military offices at Macao, and appoints the governor and all the senators, who participate in the civil authority. He has lately fixed the garrison at 180 Indian seapoys, and 120 militia-men, whose service consists in patrols at night. The soldiers are armed with sticks, and the officer alone has the privilege of wearing a sword: though he can on no occasion employ it against a Chinese. The senate of Macao is composed of the governor, who is president, and three "verendores," who are the auditors of the city finances. The revenue consists of the duty laid on merchandize, which can only be imported in Portuguese vessels. If Macao were made a free port, and had a garrison capable of defending commercial property, when deposited there, the revenue of their custom-house would be doubled, and would be adequate to all the expences of the government. But a trifling interest pertaining to the viceroy of Goa, from selling Portuguese commissions to merchants of various nations who carry on a coasting trade in the East Indies, and presents from ship-owners to the senate of Macao, raise an insurmountable obstacle to the establishment of a free trade; though this would render Macao one of the most flourishing cities of Asia, and inconceivably superior to Goa, whose utility to its mother-country will never be considerable. Besides the "verendores," there are two judges of orphans, whose department includes the administration of the property of minors, the execution of wills, the nomination of tutors and guardians, and every thing relating to successions. From their decision an appeal lies to that of Goa. Other civil or criminal causes are also cognizable, in the first instance, by two senators, who are nominated as judges. A treasurer receives the produce of the customs; and his disbursements, above a certain amount, must be sanctioned by an order of the viceroy of Goa. The most important magistracy is that of the procurator of the city, which is an intermediate office between the Portuguese government and that of China. This office is for life; that of the governor is triennial; and the other magistrates are replaced every year. An appeal lies to Goa from all the decisions of the senate, which their notorious incapacity renders

renders indispensable. This city is rendered pleasant in appearance by the fine houses occupied by the supercargoes of the different companies, obliged to winter here; and their society enlivens the place. N. lat. 22° 12' 40". E. long. 129°. Grofier. De la Perouse.

In the folio volume annexed to Sir George Staunton's "Authentic Account of an Embassy from the King of Great Britain to the Emperor of China," there is a plan of the city and harbour of Macao; containing references to all the forts, colleges, convent, and other public buildings, and places of resort; and also the depth of water, and nature of the ground, in every part of the inner harbour, as well as in the bay between the peninsula and the northern entrance into the River; taken from an accurate survey made by a gentleman who is resident on the spot.

MACAO, *Alca*, a large town of Tonquin, at the bottom of a large bay, full of islands. N. lat. 21° 30'. E. long. 107°.

MACAO, *Macaca*, in *Ornithology*. See *PSITTACUS Macao*.

MACAPÁ, in *Geography*, a town of South America, in the government of Para, on the north bank of the river of the Amazons, nearly on the equinoctial line. W. long. 52°.

MACAQUO, in *Zoology*, the name of a large species of monkey called by Mr. Ray *Cercopithecus Angolensis major*, the great Angolan monkey. See *SIMIA Cynomolgus*.

They have another species of this kind also about Angola, which may be called the black macaquo. Its only colour is black; but on many parts of the back and sides, there is a greyish cast along it: this has a tail of remarkable length, being more than two feet long. See *SIMIA*.

MACAREGUA, in *Geography*, a town of the island of Cuba; 45 miles N.W. of Havana.

MACARAUX, in *Ornithology*. See *ALCA Arctica*.

MACARIA, in *Geography*, a town on the west coast of the island of Metelin; 10 miles W. of Metelin.

MACARIANS, in *Ecclesiastical History*, the followers of Macarius, an Egyptian monk, who was distinguished, towards the close of the fourth century, for his sanctity and virtue. In his writings there are some superstitious tenets, and also certain opinions that seem tainted with Origenism. The name has been also applied to those who adopted the sentiments of Macarius, a native of Ireland, who, about the close of the ninth century, propagated in France the error afterwards maintained by Averroës, that one individual intelligence or soul performed the spiritual and rational functions in all the human race.

MACARIUS, Sr., in *Biography*, a famous anchorite of the fourth century, was a native of Alexandria. He spent sixty years in a monastery, and is said to have been a disciple of St. Anthony, the first institutor of a monastic life. He died in the year 391, when he was about ninety years of age. Fifty homilies have been attributed to him: these were first published in Greek, at Paris, in 1559. He is supposed to have been the author of many smaller tracts, "On Prayer," "Watching the Heart," "Perfection of the Mind," &c. The best edition of his pieces is that published at Leipzig in 1608. Moreri.

MACARIUS, *St.*, the *Franger*, a celebrated monk, likewise a native of Alexandria, who had 5000 monks under his direction. Of his sanctity, virtues, and abstinence, wonders are related by Palladius. He was banished by the Arians to an island inhabited by heathens, whom he converted to, what was called at that period, Christianity. He died about the year 404, when he was nearly 100 years of age. To him have been attributed "Rules for Monks,"

in 30 chapters, first published in Latin by Peter Roverius the Jesuit. Moreri.

MACARIUS, *St.*, *Desert of*, in *Geography*, a desert on the west part of Egypt, denominated in honour of a saint, to whose honour a convent of monks has been founded, anciently called "Nitria." The convent is about 50 miles N.N.W. of Cairo.

MACARON, the name of a sort of vermicelli, a paste made of flour and water, and formed in the shape of the barrel of a large quill, or the guts of small fowls.

MACARONIC, or MACARONIAN, a kind of burlesque poetry; consisting of a jumble of words of different language, with words of the vulgar tongue latinized, and Latin words modernized.

Macaron, among the Italians, as has been observed by Cælius Rhodigianus, signifies a coarse clownish name; and because this kind of poetry, being patched out of several languages, and full of extravagant words, is not so polite and smooth as those of Virgil, &c. the Italians, among whom it had its rise, gave it the name of Micaronian or Macaronic poetry. Others choose to derive it a *Macaronibus*, from *Macaro* or *Macare*, a kind of confection made of most not bolted, sweet almonds, sugar, and the whites of eggs; accounted a great dainty among the country people in Italy; which, from their being composed of various ingredients, occasioned this kind of poetry, which consists of Latin, Italian, Spanish, French, English, &c. to be called by their name.

Theoph. Folingius, a Benedictine monk of Mantua, was the first who invented, or at least cultivated, this kind of verse: for though we have a Macaronea Ariminensis in a very old letter, beginning, "Eli auctor Typhis Leoniceus atque Parafus;" yet it seems to have been the work of Guarinus Capellus Sarnas, who, in the year 1256, printed six books of Macaronic poetry, in Cabrinum Gagamonæ Regem; but as both those came out after the first edition of Folingius, which was published under the name of Merbicus Coccejus in 1520, so they were likewise much inferior to his in the style, invention, and episodes, wherewith he has enriched the history of Baldus; which makes the subject of his poem. The famous Rabelais first transferred the Macaronic style out of the Italian verse into French prose, and on the model thereof formed some of the best things in his Pantagruel.

We have scarce any thing in English in the Macaronian way, except some little loose pieces collected in Camden's *Remains*; which is no discredit to our authors: for one may say, of such pieces in general,

"Turpe est difficiles habere nugas,
Et nullus labor est ineptiarum."

But the Germans and Netherlanders have had their Macaronic poets: witness the "Certamen Catholicum cum Calvinistis" of one Martinus Hancinius Frisius, which contains about twelve hundred verses, all the words whereof begin with the letter C.

MACAROON. See MACARONIC.

MACAROWA, in *Geography*, a town of Poland, in the palatinate of Kiev; 24 miles N.W. of Kiev.

MACARACA, a town of Dalmatia, and see of a bishop, suffragan of Spalatro; situated in a territory, formerly pleasant and fertile, and convenient for commerce, but more lately deteriorated, and supposed to have arisen out of the ruins of the ancient Retinaum or Retinum; 36 miles E.S.E. of Spalatro.

MACARTNEY,

MACARTNEY, GEORGE, *Earl of*, in *Biography*, the son of George Macartney, esq. of Auchinleck in Scotland, was born in Ireland in 1737, and was educated as a fellow-commoner in Trinity-college, Dublin, where he took his degrees in 1759. Shortly after this, he travelled with the sons of the late lord Holland. This, perhaps, was his introduction to court. His education had been liberal, and he had improved the advantages which he possessed from a fortunate train of circumstances. He had an aspiring mind, and excellent talents, and was ambitious of some public employment. His own wishes were seconded by the zeal of his friends, and he was, in 1764, appointed envoy extraordinary to the empress of Russia. The object of this mission, and of the appointment of this young man, was the great importance of the commercial and political relations between Great Britain and the empire of Russia; and it was necessary, at that period, to counteract the influence of France at the Russian court.* The character and policy of that court required to be particularly studied: and hence the embassy from this country included an office that required much penetration, vigilance, and discretion, as well as insinuating manners, and an agreeable address. These qualifications were thought, by the most discerning judges, to be united in Mr. Macartney. The principal business of his mission was to negotiate a commercial treaty, for the benefit of the Russian merchants trading to Russia. Of the interests of the Russian trade he was well informed. His address surmounted every difficulty of access to the empress and her ministers: he knew how to seize the proper moment for negotiation; and he had coolness and patience to conquer every obstacle which might be opposed to his views by the artifices of others. He in a short time procured the Russian court to agree to a treaty satisfactory to the wishes of the British merchants at Petersburg, and suitable to the instructions which he had received at home. An address from the merchants of the British factory at St. Petersburg; the honour of the knighthood of the Polish order of the White Eagle, conferred by a monarch who was himself at once a man of fashion, taste, and pleasure, and a man of political talents; and the elevation to the character of ambassador extraordinary and plenipotentiary from the British court, in which he finally concluded the treaty of commerce, were, among the testimonies of approbation and respect which sir George Macartney obtained by his conduct in this diplomatic mission to the north. Thus successful and distinguished, he returned to the British court about the close of the year 1767. Early in the following year he married lady Jane Stuart, second daughter of the earl of Bute. By this marriage he had contracted a relationship to sir James Lowther, afterwards the earl of Lonsdale; and by that gentleman's interest with, or influence over, the electors, he was chosen, in the same year, one of the representatives of the borough of Cockermouth; after which we find him chosen a representative in the Irish parliament for the borough of Armagh. In 1769 sir George was nominated principal secretary to the late marquis Townshend, in the high office which he then filled of lord lieutenant of Ireland. In 1772 he was nominated by his sovereign knight of the Bath, and in 1775 went out as governor of Grenada and Tobago. He continued there till 1779, when, on the capture of those islands by the French, he was taken prisoner, and sent to France. In 1776 he had been made an Irish peer by the title of lord Macartney, baron Liffanoure, in the county of Antrim. As the loss of Grenada had not occurred from any misconduct in him, but the defence of it had indeed been signalized by the most illustrious display of all his great qualities, he met with a very gracious reception from his

sovereign on his return. In 1780 he was chosen to represent Beeralstone in the British parliament; and in the following winter he was appointed governor and resident of Fort St. George at Madras, in the East Indies: and he went without delay to discharge the functions of his appointment, where his conduct obtained such universal approbation, that, in 1785, he was appointed to the high office of governor-general of Bengal; which honour, however, after due consideration, he chose to decline, and returned to England. In 1786 he received a flattering testimony of respect from the court of directors of the East India company, who granted him an annuity for his life of 1500*l. per annum*, which was bestowed as a reward for the important services which this illustrious nobleman had rendered to the company. The same year he fought a duel with general Stuart, whom he had superseded in India. In 1788 he took his seat for the first time in the Irish house of peers; and about the same time was appointed one of the trustees of the linen manufacture for the province of Ulster, and also custos rotulorum for the county of Antrim. He was promoted likewise to the command of a regiment of dragoons in the Irish militia. In 1792 he was selected as the fittest person for ambassador from the king of Great Britain to the emperor of China. He was on the same day nominated a privy-counsellor; and in a few weeks he was raised to the rank of an Irish viscount, under the title of viscount Derwock, in the county of Antrim. He now proceeded, without delay, on his embassy, attended by sir George Staunton as his secretary, and a great train of followers and servants. A ship of war, under the command of sir Erasmus Gower, was, with smaller vessels, assigned for his voyage. Many rich presents were sent from the British to the Chinese sovereign. He arrived in safety in the Indian seas; and when his approach was announced at the Chinese court, the emperor and his minister agreed, though not without some hesitation, to receive the ambassadors and presents. In his approach to Peking, the northern capital of the empire, his lordship was obliged to direct his voyage round the South sea coast of China, by a tract hitherto almost unknown to European navigators. The opportunity of exploring that tract was regarded as almost sufficient to compensate for all the difficulties and expence of the embassy. As soon as he landed, mandarins of the highest rank were appointed to conduct him to the imperial court. His presents were accepted, and he, with all his train, were treated in a hospitable, and even sumptuous manner: but the main object of the mission was completely frustrated, *viz.* to obtain permission for the permanent residence of a British ambassador at the court of China. This was absolutely refused, and lord Macartney and his train returned over land. His lordship entered Canton in December 1793; and from thence he proceeded to Macao; and in March 1794, he sailed from that port to Europe. He arrived in England in the following September, after an absence of almost two years. On his return he was created an Irish earl; and in 1796 he was farther advanced to the dignity of a British peer, by the title of baron Macartney of Parkhurst, in Suffex. After this, he was called to the administration. In this high station, as in the other offices which he filled, lord Macartney displayed qualities which are honourable to his talents as a statesman, and his feelings as a man. His lordship died on the 31st of March 1806. Monthly and European Magazines. British and Irish Peerages.

MACAS, in *Geography*, a province of the viceroyalty of New Granada, in South America, bounded on the east by the government of Maynas, south by that of Bracamoros and Yaguafongo, and on the west the east Cordillera of the Andes

divides it from the jurisdiction of Rio Bamba and Cuenca. Its chief town bears the splendid title of the city of Macas; and this is better known than its proper ancient name of Sevilla del Oro. It lies in S. lat. $2^{\circ} 30', 40'$ E. of Quito. Its houses, which do not exceed 130, are built of timber, and thatched. Its inhabitants are reckoned at about 12,000, who, as well as those of the whole district, are generally Mestizos with Spaniards. The other towns belonging to this jurisdiction are San Miguel de Narbaes, Barahonas, Yuquipa, Juan Lopez, Zuna, Payra, Copuena, and Aguayos. The spiritual government of all these towns is lodged with two priests; one of whom, residing in the city, has the care of the four first; and to the latter, who lives at Zuna, belongs that town and the three others. At the conquest, and for some time after, this country was very populous, and, in honour of the great riches drawn from its capital, was distinguished by the name of Sevilla del Oro; but at present only the memory of its former opulence remains. The proximity of Macas to the Cordillera of the Andes occasions a sensible difference betwixt its temperature and that of Quixos adjoining to it. The winter here begins in April, and lasts till September, which is the time of summer betwixt the Cordilleras; and at Macas the fine season is in September, and is the more delightful on account of the winds, which are then mostly northward. In grains and other products, which require a hot and moist temperature, the country is very fruitful; but one of the chief occupations of the country people here is the culture of tobacco, which, being of an excellent kind, is exported in rolls all over Peru. Sugar-canes also thrive well, and likewise cotton. Among the infinite variety of trees, which crowd the woods of this country, one of the most remarkable is the florax, distinguished by the exquisite fragrant of its gum. The territory belonging to Macas also produces cinnamon trees of an excellent quality. Great quantities of copal are brought from Macas, and also wild wax of little value, because it never indurates, and the smell of it, when made into candles, and these are lighted, is very strong and disagreeable. Juan and de Ulloa's Voyage to South America, vol. i.

MACAS, a town of Africa, in the kingdom of Hoval, near the mouth of the Senegal.—Also, a river of Portugal, which runs into the Atlantic, N. lat. $38^{\circ} 51'$. W. long. $9^{\circ} 25'$.

MACASIN, a town on the S. coast of the island of Midnao. N. lat. $7^{\circ} 45'$. E. long. $124^{\circ} 16'$.

MACASSAR, or MACASSER, a sea-port town of the island of Celebes, and the principal settlement of the Dutch in this island. It gives name to one of the two great kingdoms into which the island is divided, and the island itself is sometimes distinguished by this appellation. Under the article CELEBES, the reader will find a particular account of it. Of the town captain Carteret, who visited it in 1768, gives the following account. (See Hawkesworth's Voyages, vol. i.) It is built upon a kind of point or neck of land, and is watered by a river or two, which either run through or very near it. It seems to be large, and there is water for a ship to come within half cannon-shot of the walls: the country about it is level, and has a most beautiful appearance: it abounds with plantations and groves of cocoa-nut trees, with a great number of houses interspersed, by which it appears to abound with people. At a distance inland, the country rises into hills of a great height, and becomes rude and mountainous. The town lies in S. lat. $5^{\circ} 1'$, or $5^{\circ} 12'$. E. long. by account, $117^{\circ} 28'$.

MACASSAR, *Straight of*, a passage between the islands

of Borneo and Celebes. There is in this passage a remarkable point, called by captain Carteret "Hummock Point," but in the French charts denominated "Stroomen Point." N. lat. $1^{\circ} 20'$. E. long. $121^{\circ} 39'$. This point is a good mark for those to know the passage that fall in with the land coming from the eastward, who, if possible, should always make this side of the passage. To the southward of this point there is a deep bay, full of islands and rocks, which appeared to Carteret to be very dangerous. Just off the point there are two rocks, which, though they are above water, cannot be seen from a ship till she is close to the land. To the eastward of this point, close to the shore, are two islands, one of them very flat, long, and even, and the other swelling into a hill, but both were covered with trees. Hawkf. Voy. vol. i.

MACASSAR *Poison*, in *Natural History*, called *ippo*, or *upas*, in the Macassar and Malayan tongue, is the gum of a certain tree, shining, brittle, black, and every way like stone-pitch, growing in the island of Celebes, in the South Seas; with which all the natives arm themselves in travel, having a long hollow trunk of a hard red-wood like Brazil, accurately bored, and at one end is fixed a large lance-blade of iron. Then they make a small arrow very straight, and somewhat bigger than a large wheat straw: at one end they fix it into a round piece of white, light, soft wood, like cork, about the length of the little finger, just fit for the bore of the trunk, to pass clear by the force of one's breath, and to fill it so exactly, that the air may not pass by, but against it, in order to carry it with the greater force. At the other end they fix it either in a small fish-tooth for that purpose, or make a blade of wood of the bigness of the point of a lancet, about three-quarters of an inch long, and making a little notch at the end of the arrow, they strike it firm therein, which they anoint with poison. The poisonous gum, when gathered, is put into hollow bamboos or canes, stopped up very close, and thus brought to Macassar. When they fit it for use, they take a piece of smooth turtle shell, and a stick cut flat and smooth at the end: then they take green galangal root, grate it, and with the addition of a little fair water, press the juice into a clean china dish: then with a knife, scraping a little of the poison upon the shell, dip the end of the stick in the fore-mentioned liquor, and with this dissolve the poison, to the consistence of a syrup: when this is done, they anoint the fish-tooth or wooden blade with the same stick and lay them in the sun, so that it may be baked hard. The pointed arrows thus prepared are put in hollow bamboos, close shut, and in this state they retain their virtue for a month. Birch's Hist. of the Royal Society, vol. ii. p. 44.

Rumphius, a respectable author in *Natural History*, of the 17th century, mentions a tree growing at Macassar, to which he gives the name of *Toxicaria*; and relates, that not only the red resin contained a deadly poison, but that the drops falling from the leaves upon the men employed in collecting this resin from the trunk, produced, unless they took particular care in covering their bodies, swellings and much illness; and that the exhalations from the tree were fatal to some small birds attempting to perch upon its branches. But many of the particulars of this account, though far removed from that of the supposed Upas, or poison-tree of Java by Foersch, who had been for some time a surgeon in Java, and who had travelled into some parts of the interior of the country, are given not upon the author's own observation, and may have been exaggerated. Foersch's relation of a tree so venomous as to be destructive, by its exhalations, at the distance of some miles, is compared

compared at Java to the fictions of Baron Munchausen, or as a bold attempt to impose upon the credulity of persons at a distance. Foerch's account, however, was admitted in a note to Darwin's celebrated poem of the Botanic Garden, and this circumstance led Dr. Gillan, and others belonging to Macartney's Embassy to China, to make inquiries into the fact: and the result was as we have above stated it. It is, indeed, a common opinion at Batavia, that there exists, in that country, a vegetable poison, which, rubbed on the daggers of the Javanese, renders the slightest wounds incurable; though some European practitioners have of late asserted that they had cured persons stabbed by those weapons; but not without the precaution of keeping the wound long open, and procuring a suppuration. One of the keepers of the medical garden at Batavia, assured Dr. Gillan, that a tree distilling a poisonous juice was in that collection; but that its qualities were kept secret from most people in the settlement, lest the knowledge of them should find its way to the slaves, who might be tempted to make an ill use of it. Staunton's Embassy, vol. i. p. 273. See POISON.

MACATES, in *Geography*, a town of South America, in the province of Carthage; 25 miles S.E. of Carthage.

MACAULAY, CATHARINE, in *Biography*, a distinguished writer in history and politics, the youngest daughter of John Sawbridge, esq. of Ollantigh, in the county of Kent, was born in the year 1733. She appears to have imbibed, from a very early period, a zealous attachment to the principles of liberty, which the historians of Greece and Rome had infused into her heart. The impressions made upon her mind in her youth were never obliterated. In 1760 she married Dr. George Macaulay, a physician of London. Soon after this, she commenced her career in literature, and in 1763 published the first volume, in quarto, of her "History of England, from the accession of James I. to that of the Brunswick Line." This work was completed in eight volumes in 1783: it was read with great avidity at the period of its publication, but has since fallen into so much disrepute, as scarcely ever to be enquired after. It was written in the pure spirit of republicanism, but it unquestionably had too much of party spirit in it to admit of that partiality which ought to be the characteristic of true history. While in the height of her fame, Mrs. Macaulay excited the admiration of Dr. Wilson, rector of St. Stephen's, Wallbrook, who conferred on her the unprecedented honour of placing her statue, while living, in the chancel of his church, which his successor thought himself justified in removing. Having been left a widow, Mrs. Macaulay, in 1778, married Mr. Graham, a step, in which the great disparity of years exposed her to some ridicule. In 1785 she went to America, for the purpose of visiting the illustrious Washington, with whom she had before maintained a correspondence. She died in the year 1791. Her works, besides the history already referred to, which may be regarded as the principal, are "Remarks on Hobbes's Rudiments of Government and Society;" "Loose Remarks on some of Mr. Hobbes's Positions;" the latter being an enlarged edition of the former: the object of these is to shew the superiority of a republican to a monarchical form of government. In 1770, Mrs. Macaulay wrote a reply to Mr. Burke's celebrated pamphlet entitled "Thoughts on the Causes of the Present Discontents:" and in 1775 she published "An Address to the People of England, Scotland, and Ireland, on the present important Crisis of Affairs." She wrote also "A Treatise on the Immutability of Moral Truth:" which she afterwards re-published, with much other original matter, under the title of "Letters

on Education." This work was published in 1790, at a period when men's minds were ready to admit bold theories on almost any subject, and it obtained much attention from the public. The author shewed herself an animated writer, and a shrewd and acute reasoner. It will unquestionably repay any one, interested in the subject, the labour of a careful perusal.

MACAW, MACCAW, or *Macao*, in *Ornithology*, the name of a large species of parrot, distinguished also by the length of its tail. See PSITTACUS.

MACAW Tree, in *Botany*. See COCOS.

MACAY, in *Geography*, a town of Africa, in the kingdom of Damel. N. lat. 15° 10'. W. long. 15° 55'.

MACBETH. This admirable tragedy of our matchless dramatist, Shakspeare, from the songs of the witches, as set by Matthew Lock in the time of Charles II., was regarded as a kind of opera. See DRAMATIC Music.

MACBETH, in *Biography*, an usurper and tyrant, whom the immortal Shakspeare has consigned to everlasting infamy, flourished in Scotland about the middle of the 11th century. At this period Duncan was king, a mild and humane prince, but not at all possessed of the genius and disposition for governing a country so turbulent, and so infested by the intrigues and animosities of the great. Macbeth, a powerful nobleman, and nearly allied to the crown, not contented with curbing the king's authority, carried still farther his mad ambition: he murdered Duncan at Inverness, and then seized upon the throne. Fearing lest his ill-gotten power should be stripped from him, he chased Malcolm Kenmore, the son and heir, into England, and put to death Mac Gill and Banquo, the two most powerful men in his dominions. Macduff next becoming the object of his suspicions, he escaped into England, but the inhuman usurper wreaked his vengeance on his wife and children, whom he caused to be cruelly butchered. Siward, whose daughter was married to Duncan, embraced, by Edward's orders, the protection of this distressed family. He marched an army into Scotland, and having defeated and killed Macbeth in battle he restored Malcolm to the throne of his ancestors. The tragedy founded upon the history of Macbeth, though contrary to the rules of the drama, contains an infinity of beauties with respect to language, character, passion, and incident, and is thought to be one of the best pieces, of the very best master in this kind of writing, that the world ever produced. "The danger of ambition," says Dr. Johnson, "is well described; and the passions are directed to their true ends." And the author of the *Philosophic Arrangements* says, "it is not only admirable as a poem, but one of the most moral pieces existing." Hume's Hist. Biog. Dramatica: Shakspeare Illustrated.

MACBRIDE, DAVID, M.D. a distinguished physician, was born at Ballymony, in the county of Antrim, on the 26th of April, 1726. He was descended from an ancient family of his name in the shire of Galloway, in Scotland; but his grandfather, who was bred to the church, was called to officiate at Belfast to a congregation of Presbyterians, and his father became the minister of Ballymony, where David was born. Having received the first elements of his education at the public school of this place, and served his apprenticeship to a surgeon, he went into the navy, first in the capacity of mate to an hospital-ship, and subsequently in the rank of surgeon, in which station he remained for some years preceding the peace of Aix-la-Chapelle. At this period he was led, from the frequent opportunities of witnessing the attacks of scurvy, which a seafaring life afforded him, to investigate the best method of cure for that disease, upon which he afterwards published a

treatise. After the peace of Aix, Mr. Macbride went to Edinburgh and London, where he studied anatomy under those celebrated teachers Doctors Monro and Hunter, and midwifery under Smellie. About the end of 1749, he settled in Dublin as a surgeon and accoucheur; but his youth and remarkable bashfulness occasioned him to remain a number of years in obscurity, little employed; although he was endeared to a small circle of friends by his great abilities, amiable dispositions, and his general knowledge in all the branches of polite literature and the arts. In 1764, he published his "Experimental Essays," which were every where received with great applause, and were soon translated into different languages; and the singular merit of this performance induced the university of Glasgow to confer the degree of doctor of physic on its author. The improvement introduced by Dr. Macbride in the art of tanning, by substituting lime-water for common water in preparing ooze, procured him the honour of a silver medal from the Dublin Society, in the year 1768, and of a gold medal of considerable value from the Society of Arts and Commerce in London.

For several years after Dr. Macbride obtained his degree, he employed part of his time in the duties of a medical teacher, and delivered, at his own house, a course of lectures on the theory and practice of physic. These lectures were published, in 1772, in one vol. 4to., under the title of "An Introduction to the Theory and Practice of Medicine," and a second edition appeared in 1777. It was translated into Latin, and published at Utrecht, in 2 vols. 8vo. in 1774. This work displayed great acuteness of observation, and very philosophical views of pathology, and contained a new arrangement of diseases, which was deemed of so much merit by Dr. Cullen, that an outline of it was given by that celebrated professor, in his Compendium of Nosology. Of the five classes, however, into which Dr. Macbride distributed diseases, the genera and species of the first only were detailed.

The talents of Dr. Macbride were now universally known, his character was duly appreciated, and his professional emoluments increased rapidly; for the public, as if to make amends for former neglect, threw more occupation into his hands, than he could accomplish either with ease or safety. Although much harassed both in body and mind, so as to have suffered, for some time, an almost total incapacity for sleep, he continued in activity and good spirits until the end of December 1778, when an accidental cold brought on a fever and delirium, which terminated his life on the 13th of that month, in the 53d year of his age: his death was sincerely lamented by persons of all ranks. See Edin. Med. Commentaries, vol. vii. p. 105. Cullen, Synops. Nosol. Method. vol. i.

MACCABÆUS, **JUDAS**, a valiant leader of the Jews, was the third son of Mattathias, of the Asmonæan family, whom he succeeded as general of his nation in the year 166 B.C. At this period the Jews were in a state of revolt against Antiochus Epiphanes, and Judas, with a small body of men, harassed the Syrians, Samaritans, and apostate Jews, and filled the country with the terror of his name. After some important successes, and being left master of the field, Judas marched to Jerusalem, where he purified the city and temple, the latter of which was again dedicated, and a commemorative festival, on this occasion, was instituted, which was ordered to be perpetual. The death of Antiochus gave the Jews some respite, but hostilities were soon renewed, and Judas displayed his usual vigour and military prowess. Lyfias, the commander of the Syrians, was now his chief antagonist: him he defeated and obliged to

seek terms of peace. After this the Syrian general invaded Judea a second time, and obliged Judas to take refuge in Jerusalem. He besieged the city, which would, probably, notwithstanding the valour of its defender, have been obliged to surrender for want of provisions, had not the hostile army been hastily recalled by a rebellion in their own country. After Demetrius Soter had obtained the crown of Syria, the war with the Jews was renewed: Bacchides, marching with the flower of his army, surprised Judas at the head of a small body of men, of whom, all but eight hundred, deserted at the approach of the enemy. With these he made a desperate resistance, till he fell upon a heap of slaughtered enemies. This was in the year 161 B.C.: the news of his death caused the utmost grief and consternation at Jerusalem, where a general mourning was made for him, and he was celebrated in songs, as one of the greatest heroes of the nation. His body was recovered, and interred in the sepulchre of his father at Modin. Books of Maccabees. Josephus.

MACCABEES, two apocryphal books of Scripture, containing the history of Judas and his brothers, and their wars against the Syrian kings in defence of their religion and liberties, so called from Judas, the son of Mattathias, (see **MATTATHIAS**,) surnamed *Maccabeus*, as some say from the word מַכְבִּי, formed of the initials of **מַלְכֵּנוּ יְהוֹדָה**, *q. d. Who is like unto thee, O Lord, among the Gods* (Exod. xv. 11.); which was the motto of his standard: whence those who fought under his standard were called Maccabees, and the name was generally applied to all who suffered in the cause of the true religion, under the Egyptian or Syrian kings. This name, formed by abbreviation according to the common practice of the Jews, distinguished Judas Maccabæus by way of eminence, as he succeeded his father B.C. 166 in the command of those forces, which he had with him at his death, and being joined by his brothers, and all others that were zealous for the law, he erected his standard, on which he inscribed the above-mentioned motto. Those also who suffered under Ptolemy Philopater of Alexandria, fifty years before this period, were afterwards called Maccabees; and so were Eleazar, and the mother and her seven sons, though they suffered before Judas erected his standard with the motto, from which the appellation originated. And therefore, as these books which contain the history of Judas and his brothers, and their wars against the Syrian kings, in defence of their religion and liberties, are called the *first* and *second* books of the Maccabees; so that book which gives us the history of those, who, in the like cause, under Ptolemy Philopater, were exposed to his elephants at Alexandria, is called the *third* book of the Maccabees, and that which is written by Josephus of the martyrdom of Eleazar, and the seven brothers and their mother, is called the *fourth* book of the Maccabees.

The *first* book of the Maccabees is an excellent history, and comes nearest to the style and manner of the sacred historians of any extant. It was written originally in the Chaldee language, of the Jerusalem dialect, and was extant in this language in the time of Jerom, who had seen it. From the Chaldee it was translated into Greek, from the Greek into Latin, and also into English. Theodotion is conjectured to have translated it into Greek; but it was probably more ancient, as we may infer from its use by ancient authors, as Tertullian, Origen, and others. It is supposed to have been written by John Hyrcanus, the son of Simon, who was prince and high priest of the Jews near thirty years, and began his government at the time where this history ends. It contains the history of forty years, from

from the reign of Antiochus Epiphanes, to the death of Simon the high priest; that is, from the year of the world 3829, to the year 3869; 131 years before Christ. The *second* book of the Maccabees begins with two epistles sent from the Jews of Jerusalem to the Jews of Egypt and Alexandria; to exhort them to observe the feast of the dedication of the new altar erected by Judas, on his purifying the temple. The first was written in the 169th year of the era of the Seleucidae, *i. e.* before Christ 144; and the second in the 188th year of the same era, or 125 before Christ; and both appear to be spurious. After these epistles follows the preface of the author to his history, which is an abridgment of a larger work, composed by one Jason, a Jew of Cyrene, who wrote in Greek the history of Judas Maccabæus, and his brethren, and the wars against Antiochus Epiphanes, and Eupator his son. The two last chapters contain events under the reign of Demetrius Soter, the successor of Antiochus Eupator, and contain such varieties in their style, as render it doubtful whether they had the same author as the rest of the work. This second book does not, by any means, equal the accuracy and excellency of the first. It contains an history of about fifteen years, from the execution of Heliodorus's commission, who was sent by Seleucus to fetch away the treasures of the Temple, to the victory obtained by Judas Maccabæus over Nicanor; that is, from the year of the world 3828, to the year 3843, 157 years before Christ. Culmet.

There are in the Polyglot bibles, both of Paris and London, Syriac versions of both these books; but they, as well as the English versions which we have among the apocryphal writers in our bibles, are derived from the Greek. For a further account of Judas Maccabæus, and of his brothers, whose history is recorded in the first and second books of the Maccabees, and also by Josephus in his *Antiquities*; we refer to the article *JEWS*, and also to the biographical article *JUDAS MACCABEUS*. The *third* book of the Maccabees contains the history of the persecution of Ptolemy Philopater against the Jews in Egypt, and their sufferings under it; and seems to have been written by some Alexandrian Jew in the Greek language, not long after the time of Siracides. This book, with regard to its subject, ought to be called the first, as the things which are related in it occurred before the Maccabees, whose history is recorded in the first and second books; but as it is of less authority and repute than the other two, it is reckoned after them. It is extant in Syriac, though the translator did not seem to have well understood the Greek language. It is in most of the ancient manuscript copies of the Greek Septuagint, particularly in the Alexandrian and Vatican, but was never inserted into the vulgar Latin version of the bible, nor consequently into any of our English copies. The first authentic mention we have of this book is in Eusebius's *Chronicon*. It is also named with two other books of the Maccabees in the 85th of the apostolic canons. But it is uncertain when that canon was added. Grotius thinks that this book was written after the two first books, and shortly after the book of Ecclesiasticus, from which circumstance it was called the *third* book of Maccabees. Moreover, Josephus's history of the martyrs that suffered under Antiochus Epiphanes, is found in some manuscript Greek bibles, under the name of the *fourth* book of the Maccabees. This book, ascribed to Josephus, occurs under the title "Concerning the Empire or Government of Reason;" but learned men have expressed a doubt whether this was the book known to the ancients as the *fourth* book of the Maccabees. Philostratus, Eusebius, and St. Jerom, knew the book "Concerning the Government of Reason;" and ascribed it to

Josephus, by the name of the book of the Maccabees. St. Gregory Nazianzen, St. Ambrose, and St. Chrysostom, in the characters they have given of the seven Maccabees, and of old Eleazar, have plainly followed what we find in this book. The author has enlarged and adorned the history of Eleazar, and of the seven brothers the Maccabees, who are said to have suffered martyrdom with their mother, as it has been said, chiefly on the authority of Rufinus, who has given the names of the seven brothers, and of their mother, at Antioch. (2 Mac. vi. vii.) Others, however, have supposed, that the scene of the martyrdom of the seven brethren was at Jerusalem. As it was designed for an example of terror to the Jews of Judæa, it would have lost its force, if it had been executed any where else besides that country. Those who maintain that they suffered at Antioch, allege, that their tombs were shewn there in the time of St. Jerom, and that a church, dedicated under their name, was found there in the time of St. Austin. The first of the seven brethren, as the story is related, having declared to the king that he would die sooner than violate the laws of God, was seized by the executioners, who cut out his tongue, and the extremities of his hands and feet, and tore off the skin of his hand. While still alive, after being thus mangled, he was thrown into a burning pan, heated over a fierce fire. Such is the account in 2 Mac. vii. 2. The "Government of Reason" declares, that the executioner, having stripped off his clothes, tied his hands behind his back, and whipped him with scourges, without his indicating the least sign of pain. Afterwards they fixed him upon a wheel, where, after having had his limbs shattered to pieces, he expostulated with Antiochus, reproached him for his barbarity, and insulted him on account of all his unsuccessful attempts. Then the executioner, raising the wheel upon which he was extended, and lighting a fire under it, thus consumed him by a new torture. He died, exhorting his brethren to manifest a similar constancy. The other brothers also suffered by the most cruel tortures which the king could inflict; but it is needless to recount them. The mother of these martyrs also suffered death, as some say, by throwing herself into the fire, to evade the cruelty practised on her sons, and threatened to herself. The church of Rome has celebrated a feast, August 1, in honour of these martyrs; who were the first, and for a long time the only martyrs of the Old Testament, in honour of whom altars and temples were erected; and they are the only saints of that kind, for whom there remains an office or breviary commemorative in the Roman Breviary. The sufferings of these seven brethren, and likewise of Eleazar, related 2 Mac. c. vi. are entirely omitted in the first book of Maccabees; although the author of it there writes of the Jewish affairs, and of the sufferings of the Jews in the time of Antiochus. We add that there is not any notice taken of this Eleazar, or these seven brethren, or their mother, by Josephus, in any of his authentic writings; though he had twice a fair occasion of mentioning them, once in his "History of the Jewish War," l. i. and again in his "Antiquities," l. xii. cap. 5. It is presumed that he would have mentioned a fact so remarkable, if it had really occurred. As to the work above-mentioned, "Of the Empire of Reason," which has been ascribed to him, many learned men, as Cave says, deny it to be his; and Mr. Whiston, in his English translation of all the genuine writings of Josephus, has omitted this. Dr. Lardner thinks that it was the work of some Christian. This history wants certain internal characters of credibility. The fact itself is very extraordinary, inasmuch that it is very improbable, and almost incredible. The whole story has the appearance of

a contrived fiction. The sufferers are not described so particularly as they ought to be, and the relations generally are incredible. Besides, it is improbable that these seven brothers should have been examined, tortured, and slain, one after another, in the presence of king Antiochus; for such examinations and executions are generally delegated to officers: nor is it said, or even hinted, where these persons suffered. It has been said, however, that the writer of the epistle to the Hebrews refers to this history, and thus assures us of its truth. (Heb. xi. 35.) But it is very far from being clear or certain, that there is a reference to this history in that text. Hallet, Lardner, and others, deny it. See Lardner's Works, vol. xi. p. 269, &c.

MACCHERINI, LA SIGNORA, in *Biography*, a female Italian singer, engaged as first woman at the Opera-house in 1780, on a false report of her great abilities by her countrymen in London, disappointed every hearer.

MACCHIAVELLI, NICHOLAS, a celebrated political writer and historian, was born of a good family, at Florence, in 1469. He first distinguished himself as a dramatic writer, and produced plays that were acted with great applause at Rome. Soon after he had entered public life, he was supposed to have participated in a conspiracy against the house and family of Medici; but being "put to the question" on the subject, he had the fortitude to endure the torture without uttering the slightest confession, and was set at liberty. He was afterwards raised to high honours in the state, and became secretary to the republic of Florence, the duties of which high office he performed with great fidelity. He was likewise employed in embassies to king Lewis XII. of France; to the emperor Maximilian; to the college of cardinals; to the pope, Julius II., and to other Italian princes. Notwithstanding the revenues which must have accrued to him in these important situations, he left a large family at his death in a state of indigence, a circumstance that proves he had acted with integrity, and that the love of money had no influence on his mind. He died in 1530. Besides his plays, his chief works are, 1. "The Golden Age," in imitation of Lucian and Apuleius; 2. "Discourses on the first Decade of Livy;" 3. "A History of Florence;" 4. "The Life of Castruccio Castracani;" 5. "A Treatise on the Military Art;" 6. "A Treatise on the Emigration of the Northern Nations;" 7. A Treatise, entitled "Del Principe," *the Prince*. This famous treatise was first published in 1515, and was intended as a sequel to his discourses on the first decade of Livy, which discourses are replete with just and profound reflections on the principles of popular government, and exhibit him as a warm friend of liberty; but "The Prince" has been generally regarded as the manual of a tyrant; all its maxims and counsels being directed to the maintenance of power, however acquired, and by any means. It was dedicated to a nephew of pope Leo X., was printed at Rome, republished in other Italian cities, and was long read with attention, and even applause, without censure or reply. The practice of politicians at that time was so much in unison with its maxims, that neither surprise nor detestation seems to have been excited by an open exposure of the usual arts of government. The writer's intention in this work has been a matter of much controversy; some have held him up as an abandoned promoter of tyranny, and others have maintained that he was its concealed but decided enemy, who meant to put "the people" on their guard against its machinations. A modern critic, however, thinks it probable, from the character of the man, that he wrote it without any moral purpose whatever; and merely, like a mathematician demonstrating a problem, investigated the

principles by which usurped power might be maintained, leaving the application to princes or subjects, as chance should direct. It has, nevertheless, affixed to his name a lasting stigma, and Machiavelism is become a received appellation for perfidious and infamous politics. When once the system was exposed, a multitude of opponents to it started up, in almost every enlightened country on the globe; among whom, and one of the latest, was Frederic the Great, king of Prussia, before he commenced those plans of aggrandizement, that he pursued very much in the spirit of the work which he had ably answered. Of the historical writings of Machiavel, the "Life of Castruccio Castracani" is considered as partaking too much of the character of a romance; but his "History of Florence," comprising the events of that republic, between the years 1205 and 1494, is a very valuable performance, and one of the earliest of the good Italian histories. It was written while the author sustained the office of historiographer of the republic. He has been charged with misrepresentation; but his character, as an historian, has been ably vindicated, and his style and composition, as a prose writer, are held in high estimation. His verses do not rank among the first, or even the second rate productions of Italian poetry; and his comedies, however they might appear in public representation, are not formed on the purest models. The works of this writer were collected in two volumes 4to. in 1550, and they have been republished in Amsterdam, London, and Paris. Gen. Biog. See MACHIAVELISM.

MACCLESFIELD, called in ancient records *Maxfield*, in *Geography*, a populous, corporate, and borough-town of Cheshire, England, is built on the side of a steep hill, at the distance of 18 miles from Manchester, and 166 from London. It is part of the parish of Prestbury, in the hundred of Macclesfield. Radal, earl of Chester, first constituted it a borough; and in or near the year 1261, the prince of Wales, afterwards king Edward I., made it a free borough, and granted the burghesses a mercatorial guild, and other privileges. By the conditions of the charter thus obtained, the burghesses were required to grind only at the earl's mill, and to bake at his oven. This oven, or bakehouse, is still vested in the crown, and a lease of it was granted, in 1791, for twenty-four years and a half. By a charter of queen Elizabeth's, the corporate body was to consist of 24 capital burghesses; but a later charter, from king Charles II., names a town-clerk, a coroner, two sergeants at mace, &c. as part of the corporation. Among other articles delivered into the custody of the sergeants at mace, in the year 1620, was "a bridle for a curst queane." The market, which is held on Mondays, was formerly very considerable for corn, but has declined. The annual fairs are five, principally for cloth, cutlery, toys, and pedlars' ware. The silk and cotton trade is carried on in this town to a considerable extent, there being nearly thirty silk mills, some of them on a large scale, and about ten cotton factories: a great quantity of goods of both sorts is also manufactured in private houses; there are several muslin, silk-weaving, and twist factories. The weaving of silk handkerchiefs, and the making of ferret and calico, are increasing manufactures: here are five or six dye-houses, principally for silk, a tape manufactory, and a bleaching ground. According to the returns made to parliament under the population act of 1800, the number of houses was then 1527, the number of inhabitants was stated to be 8743, of whom 8509 were said to be employed chiefly in trade, manufactures, or in handicraft. The population has since that period been considerably increased. In the year 1791, an act was passed for inclosing the commons and waste grounds within the borough and manor

manor of Macclesfield. By this act, all encroachments within the manor (except such as had occurred within sixty years, and had no buildings), were secured on certain terms to their respective possessors; the manorial rights of the crown, with respect to the soil, mines, and minerals of the several waste-grounds within the manor and borough were extinguished, with the reserve of coal-mines: as a compensation for which concessions, an allotment of 118½ acres was made to his majesty, which allotment, and the right of digging coal, were sold in 1803, under the land-tax redemption act to Charles Cooke of this town. The corporation are entitled to all springs and water-courses for supplying the town with water, from which sources, with the tolls of the market and fairs, a considerable emolument is derived. A court of record is held once a month for the liberty of the hundred, and another for the manor and forest; a court leet is also held for these jurisdictions. In former times the justices of Chester sat as justices in eyre at Macclesfield, and prisoners for felony and other crimes were tried there, and suffered the sentence of the law. After this practice was discontinued, courts were held by the king's steward or his deputy. Two sessions are now held in May and November, besides the monthly courts before-mentioned.

In a street, called Backwall-Gate, are some remains of a mansion of the dukes of Buckingham. Smith, in his description of Cheshire (1585), describes it as "a huge place, all of stone, in manner of a castle, which belonged to the duke of Buckingham, but now gone to decay." Webb, writing in 1622, says, "in this towne are yet seen some ruines of the ancient manor-house of the renowned duke of Buckingham, who (as yet report goeth) kept there his princely residence, about the time of king Edward IV., of whose great hospitality there, much by tradition is reported."

Other ancient mansions of this town were formerly occupied by families of distinction: among these was Stapleton-hall, belonging to the Stapletons of Upton; Beate-hall, inhabited by the earl of Courtown, is now a public-house; Worth-hall was the town residence of the family of Worths: and is traditionally said to have been the birth-place of archbishop Savage.

The parochial chapel of this town was originally built by king Edward I. in the year 1278; it was almost rebuilt, and greatly enlarged, in 1740. On the south side of this chapel is an oratory, or burial chapel, which belongs to the Savage family: several of whom were interred here. It now belongs to the earl of Cholmondeley. In the Legh chapel are some sepulchral memorials of the family of Legh of Lyme.

A new chapel was erected at Macclesfield in the year 1755, by Charles Roe, esq. and an act of parliament was obtained in 1779, when it was called Christ's-church, or chapel, and the living was made a perpetual cure, or benefice, to be subject to the bishop of Chester. In the chancel is a handsome marble monument by Bacon, for the founder, who died in 1781.

In this town are two meeting-houses for Methodists, and one for each of the following sects: Presbyterians, Quakers, and Independents. A grammar-school was founded here by sir John Percival, knt., and not by king Edward VI., as commonly stated. This monarch increased its revenues, by giving lands and houses in and near the city of Chester. An act of parliament was obtained, in 1768, to regulate the management, and define the constitution of this noted seminary. Four miles S.S.E. of the town is the township of Macclesfield forest. Lysons's *Magna Britannia*, vol. ii. part 2. 4to. 1810.

MACDONALD, ANDREW, in *Biography*, was born at Leith, where he was educated, chiefly by the assistance of bishop Forbes. For some time he had the charge of a chapel at Glasgow, in which city he published a novel, entitled "The Independent." He afterwards came to London, and wrote for the newspapers. His works were lively, satirical, and humorous, and were published under the signature of Matthew Bramble. He naturally possessed a fine genius, and had improved his understanding with classical and scientific knowledge; but for want of connections in this southern part of the united kingdom, and a proper opportunity to bring his talents into notice, he was always embarrassed, and had occasionally to struggle with great and accumulated distresses. He died in the 33d year of his age, at Kentish Town, in Aug. 1790, leaving a wife and infant daughter in a state of extreme indigence. A volume of his "Miscellaneous Works" was published in 1791, in which were comprised; "The fair Apostate," a tragedy; "Love and Loyalty," an opera; "Princess of Tarento," a comedy; and "Vimonda," a tragedy. Biog. Dramatica.

MACDOWAL'S BAY, in *Geography*, a bay on the W. coast of the island of Java.

MACDUFF, a considerable sea-port town situated on the banks of the Moray frith, in the parish of Gamvie, and shire of Banff, Scotland, at the distance of two miles from the county-town. Previous to the year 1732, it was merely a trifling village, composed of a few fishermen's huts, with no other harbour for their boats but a sandy creek. It is now, through the exertions of the earl of Fife, on whose property it stands, a very thriving place. The houses, which are estimated at about 300 in number, are generally built with much neatness, and arranged into regular streets of a commodious width. The population exceeds twelve hundred persons, a great proportion of whom is engaged in the extensive fisheries which have been established on this part of the coast. There are several ships belonging to this town employed in the Baltic and London trade. Many vessels from other ports likewise resort thither; the harbour, formed at the expence of the nobleman already mentioned, being considered one of the safest and most commodious in the Moray frith. As this place lies at some distance from the parish church, the same noble individual has also erected a chapel of ease here, and pays a suitable salary to the clergyman settled in it. A great variety of little fishing villages lie along the shore on both sides, and on the opposite bank of the river Doveran.

MACE, in *Ancient Armoury*, a weapon formerly much used by the cavalry of all nations, and likewise by ecclesiastics, who, in consequence of their tenures, frequently took the field, but were, by a canon, forbidden to wield the sword. The mace is commonly of iron; its figure much resembles a chocolate-mill. Many specimens may be seen in the Tower of London, and other armouries. It was not out of use long after the invention of hand-guns; for we read of its having been used by most nations more than 100 years ago; and in a medley, it is said, they may be more serviceable than swords; for when they are guided by a strong arm, we find that the party struck with them was either felled from his horse, or, having his head-piece beat close to his head, was made to reel on his saddle, with the blood running plentifully from his nose. This kind of mace, which is the same as that used by the Turks, is improperly called by some military writers the club of Hercules; the club given to that demi-god by the Grecian statuary, being a huge knotty limb of a tree. Father Daniel has engraved two weapons, shewn in the abbey of Roncevaux,

as the maces of those famous heroes of romance, Roland and Oliver, who are said to have lived in the time of Charlemagne. One is a large ball of iron, fastened with three chains to a strong truncheon, or staff, about two feet long; the other is of mixed metal, in the form of a channelled melon, fastened also to a staff by a triple chain: these balls weigh eight pounds. At the end of both the staves are rings for holding ends or leathers to fasten them to the hand. Contrivances like these, except that the balls were armed with spikes, were long carried by the pioneers of the trained bands, or city militia: they are generally called "Morning Stars." The morning star, or Morgan stern, was a weapon formerly used for the defence of trenches. It was a large staff, banded about with iron, like the shaft of a halbert, having an iron ball at the end, with cross iron spikes.

At present the mace is generally made of the precious metals, and highly ornamented and used as an emblem of the authority of the officers of state before whom it is carried.

MACE, THOMAS, in *Biography*, one of the clerks of Trinity college, Cambridge, in the seventeenth century, of quaint and singular memory, published in folio, 1676, a treatise, entitled "Musick's Monument; or, a Remembrance of the best practical Musick, both Divine and Civil, that has ever been known in the World;" a work that must not be forgotten among the curiosities of this period. It is impossible to describe the style of this original book by any choice or arrangement of words, but the author's own. The work is divided into three parts; the first treats of psalm-singing and cathedral music; the second, of the noble lute, "now made easy, and all its occult, locked-up-secrets, plainly laid open; shewing a *general way* of procuring *invention* and playing voluntarily upon the lute, viol, or any other instrument, with two pretty devices, &c. In the third part the *generous viol*, in its *rightest use*, is treated upon; with some *curious observations*, never before handled, concerning it, and music in general."

In psalm-singing the author recommends *short-square-even and uniform ayres*, and is "bold to say that many of our old psalm-tunes are so *excellently good*, that art cannot mend them or make them better." In speaking of the difficulty of singing in tune, even with a good voice, he observes, that "with an *unskillful-inharmonious-coarse-grained-harsh-voice*, it is impossible. 'Tis *sad* to hear what *avbining, toling, yelling, or screeking* there is in our *country congregations*, where, if there be no organ to compel them to harmonical unity, the people seem *affrighted* or *distracted*."

The liberal use of compounds by the ingenious master Mace gives his language a very Grecian appearance. He doubts not but that there are "many *rational-ingenious-well-composed-willing-good-Christians*, who would gladly *serve God* aright, if possibly they knew but how;" and therefore he advises the purchase of an organ of thirty, forty, fifty, or sixty pounds; and then, "the clerk to learn to *pulse* or *strike* the psalm-tunes, which he offers himself to teach for thirty or forty shillings; and the clerk afterwards may instruct all the boys in the parish for a shilling or two a-piece to perform the business as well as himself. And thus by *little and little*, the parish will *swarm* or abound with organists."

The lute and viol are master Mace's favourite instruments, concerning the effects of which, and, indeed, of music in general, he is a great rapturist. On the lute, though "he had occasion to *break both his arms*, by reason of which he could not make the *nerve-shake well*, nor strong; yet, by a certain *motion of his arm*, he had gained such a *contentive*

shake, that his scholars asked him frequently how they should do to get the like?"

We shall not attempt to recreate our readers with more extracts from this matchless, though not scarce, book; but recommend its perusal to all who have taste for excessive simplicity and quaintness, and can extract pleasure from the sincere and undissembled happiness of an author, who, with exalted notions of his subject and abilities, discloses to his reader every inward working of self-approbation in as undisguised a manner, as if he were communing with himself in all the plenitude of mental comfort and privacy. We shall, however, present such readers with an advertisement from good master Mace, that was written on his arrival in London, 1690, fourteen years after the publication of his book. We found it in the British Museum, N^o 5936, in a collection of title-pages, devices, and advertisements.

An Advertisement.

"To all Lovers of the best Sort of Musick."

"Men say the times are strange—'tis true:

'Cause many strange things hap to be.

Let it not then seem strange to you

That here one strange thing more you see."

"That is, in Devereux-court, next the Grecian coffee-house, at the Temple back gate, there is a deaf person teacheth music to perfection; who, by reason of his great age, v. 77, is come to town, with his whole stock of rich *musical furniture*, v. instruments and books to put off, to whomsoever delights in such choice things; for he has nothing light or vain, but all *substantial* and solid music. Some particulars do here follow:

"1. There is a late invented ORGAN, which (for private use) excels all other fashioned organs whatever; and for which, *substantial-artificial reasons* will be given; and (for its beauty) it may become a nobleman's dining-room.

"2. There belongs to it a pair of fair, large-sized *confort-viol*s, chiefly fitted and suited for That, or confort use; and 'tis great pity they should be parted.

"3. There is a *pedal harpsicon* (the absolute best sort of *confort harpsicons* that has been invented); there being in it more than twenty *varieties*, most of them to come in with the foot of the player, without the least hindrance of play (exceedingly pleasant). And

"4. Is a single *harpsicon*.

"5. A new invented instrument, called a *dyphone*, v. a *double lute*; it is both *theorbo* and *French-lute* complete; and as easy to play upon as any other lute.

"6. Several other *theorbos*, *lutes*, and *viols*, very good.

"7. Great store of choice collections of the works of the *most famous composers*, that have lived in these last hundred years, as Latin, English, Italian, and some French.

"8. There is the *publisher's own Musick's Monument*; some few copies thereof he has still by him to put off; it being a subscribed book, and not exposed to common sale. All these will be sold at very easy rates, for the reasons aforesaid; and because (indeed) he cannot stay in town longer than four months (exactly)."

He farther adds, "if any be desirous to partake of his experimental skill in this *high-noble-art*, during his stay in town, he is ready to assist them; and (happy) they may obtain that from him, which they may not meet withal elsewhere. He teacheth these five things, v. the *theorbo*, the *French-lute*, and the *viol*, in all their excellent ways and uses; as also *composition*, together with the *knack* of procuring *invention* to young composers (the general and greatest difficulty they meet withal), this last thing not being attempted

tempted by any author (as he knows of), yet may be done; though some has been so wise (or otherwise) to contradict it:

"Sed experientia docuit."

"Any of these five things may be learned so understandingly, in this little time he stays (by such general rules as he gives, together with *Musick's Monument*, written principally to *such purposes*), as that any aptly inclined, may (for the future) teach themselves without any other help."

MACE, FRANCIS, a learned French priest, was born at Paris about the year 1640, and being designed for the church, he pursued his studies with that view at the university of his native city, where he took his degrees. His first public employment was that of secretary to the council for managing the domains and finances of the queen, consort to Lewis XIV. It was not till the year 1685 that he took holy orders, when he was immediately appointed canon, vestry-keeper, and rector of the royal collegiate and parochial church of St. Opportune, at Paris. He was a very diligent student as well in profane as in sacred literature, and was celebrated for his popular talents as a preacher. He died in 1721, leaving behind him a great number of works that do honour to his memory, of which we shall mention "A Chronological, Historical, and Moral Abridgment of the Old and New Testament," in 2 vols. 4to.; "Scriptural Knowledge, reduced into Four Tables;" a French version of the apocryphal "Testaments of the Twelve Patriarchs;" of which Grosseteite, bishop of Lincoln, gave the first Latin translation, Grabe the first Greek edition, from MSS. in the English universities, and Whittan an English version; "The History of the Four Ciceros," which abound in learned and curious enquiries, and intended to prove, from the testimony of Greek and Latin historians, that the sons of Cicero were as illustrious as their father. Moreri.

MACE, in *Commerce*, a small gold coin, current in Sumatra, and some other East India islands. It weighs nine grains, and is worth about 14d. sterling. Sixteen mace are equal 64 copangs = 4 pardows = a tale: and 2500 small pieces of tin or lead, called cashes, usually pass for a mace.

MACE, *Macis*, is a pretty thick, tough, unctuous membrane, reticular or variously chapt, of a lively reddish-yellow colour, approaching to that of saffron, enveloping the shell of the fruit, whose kernel is the nutmeg. The mace, when fresh, is of a blood-red colour, and acquires its yellow hue in drying. It is dried in the sun, upon hurdles fixed above one another, and then, as it is said, sprinkled with sea-water, to prevent its crumbling in carriage.

Mace has a pleasant aromatic smell, and a warm, bitterish, moderately pungent taste; it is a thin and flat membranaceous substance, of an oleaginous nature, and of a yellowish colour. We meet with it in flakes of an inch or more in length, which are divided into a multitude of irregular ramifications; it is of an extremely smooth surface, and of a tolerably close texture, yet friable, and very easily cut to pieces. It is of an extremely fragrant, aromatic, and agreeable smell, and of a pleasant, but acrid and oleaginous taste; it is to be chosen new, not dry, and of a fragrant smell, tough, oleaginous, and of a good yellow. The people who collect the nutmeg fruit cut it open, and throw away the pulpy substance, or external coat; they then see the mace covering the nutmeg, wrapping itself every where round its outer woody shell. The mace is at this time of a red colour; they take it carefully off from the nutmeg, and lay it in the sun for the whole day. In this time its colour, from a strong blood-red, becomes dusky; it is after this

carried to another place, where the sun has less power, and there exposed again to its rays, the few hours they reach thither. By this means it dries gently, and remains tough, and retains its fragrant and colour in a great degree: if it were dried more hastily, it would be whitish, brittle, and would lose much of its smell; after this, it is slightly sprinkled over with sea-water, and then put up into bales in which it is pressed down firm and close, by way of preserving its fragrance and confidence.

It is of an astringent and drying nature, and is used as a corrector in cardiac and cathartic compositions. In its general quality it is nearly similar to the *nutmeg*, which see; the principal difference consists in the mace being much warmer, more bitterish, less unctuous, and sitting easier on weak stomachs; in its yielding by expression a more fluid oil, and in distillation with water a more subtle volatile one. Lewis's Mat. Med.

MACE, *Oil of*, is a kind of sebaceous matter, said to be expressed from the nutmeg, and appearing to be a mixture of the gross sebaceous matter of the nutmeg, with a little of the essential or aromatic oil; both which may be perfectly separated from one another by maceration or digestion in rectified spirit, or by distillation with water. The best sort of this oil is brought from the East Indies in stone jars, and is somewhat soft, of a yellow colour, and of a strong agreeable smell, much resembling that of the nutmeg itself. There is another sort brought from Holland in solid masses, generally flat, and of a square figure of a paler colour, and much weaker smell. Lewis.

MACE, *Reed*, in *Botany*. See TYPHA.

MACEDA, in *Geography*, a town of Spain, in the province of Galicia; five miles S.E. of Santiago.

MACEDO, FR. FRANCISCO DE SANTO AGOSTINHO, in *Biography*, a learned Portuguese, was born at Coimbra in 1597, and at a very early age discovered premature and extraordinary proofs of memory and imitation. At the age of eleven he could repeat the whole of the *Aeneid*, and compose good Latin verses. He joined the company of the Jesuits, which he quitted, and entered the Franciscan order in the reformed province of St. Antonio. When the Braganzan revolution broke out, Macedo espoused the patriotic side, was called to political exertions, and visited Rome, Paris, and London with ambassadors of Joam IV. As he advanced in years he retired to Rome, where he obtained the professorship of ecclesiastical history, and other offices in the college De Propaganda Fide; for some time he performed all the high duties attached to his several stations with credit, and to the entire satisfaction of the pope, whose favour he forfeited for refusing to expunge a word in an epitaph written upon a servant of his holiness. At Rome, and also at Venice, he engaged in many learned disputes with characters of the first literary reputation. To all his opponents Macedo replied most readily and without the smallest embarrassment, correcting their false quotations, and confuting their arguments; and he is said to have crowned the whole by reciting a thousand extempore verses, and an epigram in praise of the city of Venice, which epigram was by order of the republic written under his picture, and placed in the library of St. Mark. From the wonderful powers of his memory he obtained the title of the walking Cyclopaedia. He died in 1681, at the great age of eighty-five. He left a vast multitude of works either in manuscript or in print; he estimated the number of verses which he had made at a million and a half. Of this prodigious number, says Mr. Southey, nobody now reads a single line. Gen. Biog.

MACEDONIA, in *Ancient Geography*, a country of Europe, distinguished by various appellations, belonging to one or other of its districts, according as the people who inhabited those districts happened to prevail. In the most ancient times it took its name from *Æmathia*, a denomination derived from *Æmathus*, a prince of great antiquity; but afterwards the Greeks called it Macedonia, either from king Macedo, a descendant, as some pretend, from Deucalion, or, as others say, by an easy change of Mygdonia, the name of one of its provinces, into Macedonia. Its boundaries have been very various. Sometimes more extended and sometimes more confined, according to the good or bad fortune of its reigning princes. It was bounded originally on the E. by the *Ægean* sea, on the S. by Thessaly and Epirus, on the W. by the Adriatic, or the Ionian sea, and on the N. by the river Strymon and the Scardian mountains, afterwards by the river Nestus, or Nestos. Pliny says, that no less than 150 different nations were seated within its territory, and *Mela* tells us, that it had as many nations as cities; but in the time of Ptolemy, it appears from his geography, that this number was very considerable. Livy (c. xxx.) comprehends the federal divisions of Macedonia under four principal parts, which he describes as follows: "Parva pars, Bitabæ habet fortissimæ viros: trans Nestum amnem inchoant et circa Strymonem, &c." This part was fertile, contained mines, and had for its principal town Amphipolis, which guarded the entrance into Macedonia, towards the east. "Secunda pars, celeberrimæ urbes Thessaloniceam et Cassandriam habet." To this part was joined Pallana, a country very fertile, and abundant in grain, and having good ports. "Tertia regio, nobiles urbes Edeffum et Beream, et Pellam et Vettiorum bellicosam gentem: incolæ quoque permultos Gallos et Illyrios impigros cultores." "Quartam regionem Eordæi, et Lyncestæ, et Pelagones incolant. Iuncta his Atintania et Stymphalis et Elimiotis." Cellarius distinguishes "Macedonia propria," from Macedonia adjuncta. Macedonia propria, or Macedon proper, contains the following parts. 1. In this part were the *Alonipi* in the north, where the mountains Hemus and the Scardus join. This country is called *Almonia* by Thucydides; and Livy places here mount Boreas. *Pelagonia*, called by Strabo *παράλιος*, because it contained three towns, though Ptolemy assigns to it only two, is the fourth region of Livy, supposed to be the same with *Pœonia*. *Lyncæis* or *Lyncæis*, inhabited by the Lyncestæ, lay to the S.W. of Pœonia. The chief town was Heraclea. *Eordæi*, inhabited by the Eordæi, was situated W. of the Lyncestæ, or between the country of the Toulanti and Oreites. North of these was the territory of the Daifacæ, whose chief towns were Lyechnides and Ecia. The former was called Lychaidia by Polybius, and was pleasantly situated near a lake of the same name. It is now called Ochrida. To this part belonged also a portion of *Elimiotis*; the rest was in Illyria, as well as Candavia. 2. The second part was comprised between the rivers Erigon and Axios. Here are found the famous towns of Edeffa, Berea, and Pella. Livy places in this part the famous nation of Vettii. Towards the north lies a portion of Pœonia, called *Deurbis*, which, according to Strabo, had three towns, *viz.* Bryantium, Abderonæ, and Stybera. In the part of Pœonia, which was on this side of the Axios, was Armisfa, which, according to Thucydides, was the first town of the kingdom of Macedonia. *Æmathia* was the most considerable part of Macedonia, as formerly to have given it its name; in which country we find Tyrissa, Seydra, Meyza; and since *viz.* *Thessalonica*, Cythrus, Idomene, Gortyna or Gortyna, Argæ, and Pella. Towards the sea was the small

country, called *Bottia*, or *Bottia*. As Herodotus attributes to this small country the towns of Ichne and Pella, Cluvier conjectures that *Æmathia* was enlarged by its encroachments on this province. *Pieria* lay to the south of this small country, and in process of time comprehended Bottia. In Pieria were the towns of Alorus, Methone, Pida, called Citron, Dium, and others less considerable. The river Empeus, flowing from the valleys of mount Olympus, discharged itself into the sea, south of Dium, and at its mouth was Phyla, a strong town, built by Demetrius Gonatas. 3. The third part of Macedonia, according to Cellarius, was comprehended between the rivers Axios and Strymon; and this is the second according to the distribution of Livy. In this part are found *Amphaxitis*, E. of the mouth of the Axios, on the Thermaic gulf. The most considerable town was Therna, which afterwards took the name of Thessalonica, and is now called Salonichi. *Mygdonia* lay to the N. of the Thermaic gulf, but did not extend to the sea. Here were the towns of Antigonea and Stola, Phryca, Perpillas, Afforus, and Xylopolis; and by extending this part towards the south, it will be made to comprehend the towns of Apollonia and Arethusa. Thucydides places immediately after Mygdonia, *Grestonia*, *Andania*, and *Bisaltia*. *Antebus* probably derived its name from the town of Anthemus, placed by M. d'Anville towards the E. of Amphaxitis, near the source of the Rellius. *Grestonia* or *Orgetonia*, was situated N.E. of Amphaxitis, and had a town of the same name. The Echodorus had its source in this country, and ran from hence into Mygdonia. *Sintice* and *Bisaltia* lay towards the N. and N.E. of Grestonia, upon the Pontus, between the mountains, and had a town named Heraclea Sirtica. *Bisaltia* was a country inhabited by the Bisaltæ, who occupied a territory near the river Strymon. Another considerable part of Macedonia was comprehended in a peninsula, which projected between the Thermaic gulf to the west, and the Strymonic gulf to the east. Towards the N.W. was the small country called *Grestia*; southwards from the sea to the E. was Chalcidica, terminated by three long peninsulas, passing in a direction from N.W. to S.E. The most westerly was called *Pallana*, which had formerly borne the name of *Phlegra*; the next was *Sithonia*; and the third was a peninsula joined to the continent by a tongue of land, in which was situated mount Athos. On the western coast is *Grestia*, with its towns Ælia or Ævea, Gigonus, Smyla, Antigonea, Combrea, and Lipaxos or Lipaxus. Upon the isthmus which connects *Pallana* with the continent, was the town called Potidea, and afterwards Cassandra; to the W. were the towns Sana, Menda, Seione, and Therambus or Therambus. At the extremity of the S.E. was *Cassandracum Promontorium*, together with a place of the same name. Upon the eastern coast were Æga and Agathis. Between the eastern coast of *Pallana* and the western coast of *Sithonia*, the sea formed a gulf, called *Toroneus Sinus*; at the bottom of this gulf, on an eminence, was the town of Olynthus, separated from the gulf by the Bolyca palus, a marsh into which were discharged the two small rivers Olynthus and Amnias. Upon the western coast of *Sithonia* were the towns of Micyberna, Sermyla, Galepus, and Torone, whence the Toroneic gulf derived its name. At the western extremity of this peninsula was the *Promontorium Derris*, and at the S.E. point was the *Promontorium Amphipolis*. On the eastern side were Sarga, Singus, Pidaurus, and Asfa, at the mouth of the Chabrias. The gulf, which bathed this coast, had taken its name from Singus, situated at the entrance of a very large bay. The peninsula, in which stood mount Athos, had several places situated along

MACEDONIA.

the sea coast. On the coast towards the N. were Sana, Cleonæ, Thyssum, near the *Promontorium Nymphæum*. Upon the coast towards the S.E. at the foot of the mountain, was Apollonia, and the promontory that bore the name of *Acro-Athos Promontorium*. Towards the N.W. were the towns of Olophyxus, Dium, and Acanthus, situated in a bay in which Xerxes would have brought his ships into the Singitic gulf when he meant to cut through Athos, in order to prevent the necessity and danger of doubling the two promontories, Acro-Athos and Nymphæum. To the N., on the same coast, are Stagyra, Arna, Arethusa, Bromiscus, Argilus, and Eion at the mouth of the Strymon, where also was Amphipolis.

The *Macedonia adjecta* of Cellarius, was that which was taken from Thrace in the time of Philip, and extended from the river Strymon on the W. to the Nyssus on the E. Amphipolis, the port of which was Eion, belonged to this part. Cluverius places also in this part the town of Berga, but it really lay W. of the river. From Berga was derived the proverbial expression *Bergaizare* *id est*, nihil veri dicere, for exaggeration, or saying any thing that was scarcely credible. To the E. of Strymon was Gazolus; on the sea-coast, beyond Eion, were Phages, Gapselus, Æsymba, and Neapolis. In the inland territory was Philippi, formerly called Crenides and Datus, and which under its latter name became a Roman colony; and towards the W. Drabescus, Triuilum, Domerus, &c.

Macedonia was intersected by many Roman ways, the most ancient of which was called *Via Egnatia*. It was thought to have been a continuation of this Roman way, that terminated at Brundisium; it commenced at Dyrrachium, whence it passed by Hydrantium to Aulon, on the coast of Epirus. From each of these towns it branched off to Claudiana. From this place it passed to Lichnidus, belonging to the Daflaretii, and thence turning to the S., it passed by Heraclæa, belonging to the Lynceæ, by Edessa, Pella, Thessalonica, Apollonia, Amphipolis, Philippi, Neapolis, and the rest of Thrace, as far as Cypselus or Cypela on the Hebrus. Some authors have continued it as far as Constantinople.

Ptolemy extends Macedonia as far as the Ionian sea, and assigns as its boundaries on the N. Dalmatia and Mælia, and on the west Thrace. On the coast he places the Taulanti, then the Elymiotæ, Orestis, Edonis and Odomantice on the Strymonic gulf, and on the same gulf Amphaxitis, then Chalcidica, Paraxia on the coast, Pieria on the Thermaic gulf, the Pelasgioti on the coast, Phlitiotis on the Pelasgic gulf; and northwards, towards the W., &c. the Albani, the Almopi, Orbelæ, the Eordati, the Edraci, Joranum, Sintices, the Daflaretii, Lyceæ, Pelagonia, Bifaltie, Mygdonia, Emathia, the Parthyæi, Stymphaliæ, the Eltioti, and the Thessalii. The islands which he assigns to Macedonia were Saso in the Ionian sea, and in the Ægean sea, Lemnos with its two towns Myrina and Hephæstia, Scythos with a town of the same name, Scopelos, and Seyros with a town of the same name.

According to M. de l'Isle's map of Greece, the extent of Macedonia from N. to S. was about 160 miles, and from W. to E. about 220. Its form was very irregular; but its situation was excellent, its shores being washed on the E. by the Ægean, and on the W. by the Ionian seas: but these advantages with regard to navigation and commerce, were never well improved; as the Macedonians were never powerful at sea, notwithstanding the many noble bays and excellent harbours which their coast afforded.

Among the most considerable mountains of this country, we may reckon the great ridge, which traversed the northern part, called the Scardian mountains. In this part also was

situated mount Pangæus, which was lofty and well covered with wood, and which was more valuable on account of its mines of gold and silver. From Thrace it was divided by mount Hæmus, which towards the W. joined the Scardian hills. Athos, in the Chalcidian region, was one of the most celebrated mountains in the world. (See *ATHOS*.) Olympus was also another mountain, that was so lofty as to reach almost the confines of heaven, whence the poets took the liberty of making it the seat of the gods. (See *OLYMPUS*.) The Scardian hills and mount Athos were well covered with woods; and, indeed, the whole kingdom of Macedonia, being every where intermixed with mountains and rising grounds, abounded with all sorts of trees, that were valuable on account either of timber, fruit, or shade. The seas that adjoined it were the Adriatic, which afforded several safe ports, besides the great haven of Epidamnus, now Durazzo; and the Ægean sea, which opened to this country not only the trade of Greece, but that of Asia. Its bays were spacious, and four of them were especially remarkable; viz. Sinus Strymonicus, which enclosed in its bosom the island of Thafus, and is now called Golfo di Contessa:—Sinus Singiticus, having on one side mount Athos, and on the other a long slip of land, once full of rich and populous towns, now styled Golfo di Monte Santo:—Sinus Toronaicus, having the ridge of land just mentioned on one side, and part of the region Paraxia on the other, now called Golfo di Aiomama:—and Sinus Thermæus, 60 miles in length, now called the gulf of Salonichi. Of the rivers of Macedonia, those that fell into the Adriatic were the Panyasus, the Apfus, the Laous, called also Æas and Aous, and Celydaus or Pelychus, which is considered as the boundary between Macedon and Epirus. The rivers that discharged themselves into the Ægean sea were the Aliæmon, the Erigon, the Axios (see *AXIOS*), and the Strymon, the ancient boundary between Macedon and Thrace, but since the time of Philip this boundary has been the Nessus. As to the lakes of Macedonia, besides those formed by the overflowing of the river Strymon, and the junction of the rivers Axios and Erigon, there is almost in the centre of the country, not far from the Candavian mountains, a large and famous lake, called the lake of Lychnidus, or the lake of Prespa. There is also another lake in the province of Mygdonia; and a third near the ancient city of Sintia, called afterwards Heraclæa Sintica.

The climate of Macedonia was salubrious and favourable to longevity; the soil was generally fertile, especially on the sea-coast, producing in abundance corn, wine, and oil; but the principal riches of Macedonia consisted in its mines of almost all kinds of metals, but more particularly of gold. The Romans, when they reduced Macedonia into a province, refrained the inhabitants from digging or refining gold or silver, but left them at liberty with regard to any other metal. In ancient times Macedonia abounded with horses above all the other countries of Greece. Three hundred stallions, and 30,000 mares, were kept in the royal stud near Pella.

MACEDONIA, History of. This country was originally inhabited by many nations. Those from whom the race sprung, which from small beginnings became lords of Greece, were Argives. Under the conduct of Caramus, who was descended from Heracles by his son Temenus, they came into this country about 814 years B.C. and established themselves by their arms. Their dominion was afterwards considerably enlarged by their prudence as much as by their valour; for erecting no trophies after their victories, and treating those whom they had subdued with the tenderness of brethren, they engaged the affections of the conquered, with whom they associated as one people, and thus various tribes

MACEDONIA.

were reduced into one nation. Although the Macedonians were always governed by kings, they preserved as great or even greater liberty than most of the Grecian commonwealths: their monarchs always ruling them according to the maxims of natural equity. This was the original constitution, and it may be said, very much to their honour, that it was not subverted but with the kingdom. In cases where the punishment was capital, the cause was heard by the army or by the people; and till they condemned the party, the king did not pretend to put him to death. Alexander in many instances adhered to this custom; although a rigid regard to the constitution of his country was not always the ruling principle in a Macedonian monarch, as we are informed by Polybius. The throne was hereditary; and continued in the race of Caranus, till the slaughter of Alexander's family; and in general the eldest son succeeded. The ancient kings of Macedon made no ostentatious display of regal dignity. Alexander the Great was the first who wore a diadem and rich robes of state, which were transferred to his successors. The people were loyal and attached to their prince. With regard to marriage, the Macedonian kings were not very scrupulous; as they had frequently several wives and a number of concubines. In the education of their children they were very exemplary, their sons being placed under the tuition of the best masters, who inculcated the love and practice of great and glorious actions; and their daughters were initiated in the practice of every virtue. In the conduct of their own affairs they were moderate and prudent, affecting no magnificent entertainments, condescending to their subjects, and habituated to business. Their chief diversion was hunting. These princes were generally learned, or at least patrons of learned men. In the most solemn acts of their administration, they maintained such a decorum as rather endeared them to than awed their subjects. They heard causes in person, and suffered those who pleaded before them to speak with the greatest freedom. After their deaths, the Macedonian kings were interred in the royal sepulchre; and as they were beloved whilst they lived, the people mourned for them when they died as for their common parents.

The Macedonians, with respect to religion, followed the opinions embraced by the rest of the Greeks, worshipping many gods, and indulging a great variety of ridiculous rites. Jupiter, Hercules, and Diana, were the objects of their special reverence. They were strict in their morals, and temperate in their ordinary mode of living, but magnificent and self-indulgent in their feasts. At these feasts no women were admitted; and it was an inviolable rule that nothing should be divulged, that passed at their convivial meetings. They used their captives as concubines, but held it dishonourable to marry them. In capital cases, judgment was given by the voice of the army; in cases of doubt torture was allowed; and their punishments were various. Sometimes, but chiefly on extraordinary occasions, and in conformity to foreign customs, the criminal was thrust through with darts, or crucified with his head downwards, or thrown chained into rivers; however, the most frequent punishment, and that which seems to have been legal, was stoning to death, in which the army, as they had been constituted judges, were executioners.

As there were several mines in Macedonia, there was under its several kings a variety of silver and gold coins; of the latter sort were the Philippiæ, so called from bearing the bust of Philip, the father of Alexander. These were for a long time the most current coins in Greece.

The language of the Macedonians differed very much from the several dialects of the Greek; inasmuch that the natives of Greece, who served in Alexander's army,

were not able to understand a discourse delivered in the Macedonian tongue.

Their military discipline deserves particular notice, as it served to raise them from being a mean and obscure people to be lords of Greece. At first they were brave and warlike, and by degrees they became invincible from the union of superior courage with military skill. Their army consisted of their natural born subjects, their allies, and mercenaries. The natives served at their own expence, and contented themselves with the spoil of their enemies. The allies were composed of the respective quotas of Thessaly, Pæonia, and other dependent provinces, and of auxiliary troops furnished by Greece. The mercenaries were soldiers of fortune, who served only for pay. The Thessalians furnished horse, and there were also many troops of Macedonian cavalry; the discipline of which was so strict, that if any of the private men lost their horses, either by sickness or in action, their officers were obliged to furnish others out of their own stables. The infantry were composed of three bodies, *viz.* the light-armed, the peltastæ, who were better armed, and the heavy-armed soldiers, of whom the phalanx was composed. These troops were adapted to all sorts of enterprises. The heavy-armed foot were generally drawn up in the centre of the army, in a square body, called the phalanx. This consisted, according to Polybius, of 16 in flank, and 500 in front, all pikemen, the soldiers standing so close, that the pikes of the fifth rank reached their points beyond the front of the battle. As to the arms of the Macedonians, they were offensive and defensive. At first their targeteers had only wooden bucklers, or such as were made of a kind of wicker; but in process of time, they had them of leather and brass. Their swords, like those of other Greeks, were made both for pushing and cutting; and they also made use of daggers. Their spears were both long and short; they had also breast-plates made of linen quilted to a proper thickness, and a particular kind of military shoe. When the army was in the field, the phalanx was drawn up generally in the centre. The horse and light-armed troops in two lines on the right and left. Immediately before battle, the king or general usually made an oration, of which the soldiers expressed their approbation by clashing their arms; but if it did not affect them, they remained silent. When they charged, they exclaimed, *Alala!* *Alala!* and when they desired quarter, they held their spears aloft in the air. All authors agree in representing the hardiness, frugality, and good order of the Macedonian troops. Their camp was always fortified with a good ditch and entrenchment. Their tents were small, made of skins, and when folded up, they made use of them in passing rivers. The king's tent was pitched in the centre, and consisted of two rooms, one in which he slept and the other in which he saw company; and before the door of it, his guards did duty. The military signals of the Macedonians were either trumpets or fires. On a march the cavalry and light-armed troops took post in the van, the phalanx in the centre, and the baggage in the rear, unless they apprehended a sudden engagement; in which case they marched in order of battle. Every soldier had a kind of knapsack, and the army was attended with a certain number of carts and waggon; but the Macedonians did not allow either women or useless servants to follow the camp. The plunder was sometimes distributed among the soldiers, at other times collected and sold for the use of the king, or for the army. In quarters, the army was preserved from corruption, and its discipline maintained by military games, in which rewards, both honorary and lucrative, were bestowed. After victories, the kings were accustomed to reward all who distinguished themselves.

Those

Those who died in the service were honoured with public monuments, and their children and relations were freed from tribute. In all other respects, they were treated with the greatest humanity and condescension; and when the time limited for their service expired, or their wounds rendered them incapable of serving, they were dismissed, with ample provision for themselves and families, that they might enjoy the fruits of their labour, and by living in ease and peace, excite younger and more robust men to come cheerfully in their room.

The kingdom of Macedon commenced with Caranus in the year 814 B.C. and continued 646 years, till the battle of Pydna.

A TABLE of the kings of Macedon from its establishment to its dissolution.

B.C.	Kings.
814	- Caranus.
786	- Canus.
774	- Thurimas.
729	- Perdiccas I.
678	- Argæus I.
640	- Philip I.
602	- Ætropas.
576	- Alecdus or Alcetas.
547	- Amyntas I.
497	- Alexander I.
454	- Perdiccas II.
413	- Archelaus, said to be the patron of learning.
399	- Amyntas II.
398	- Paufanias.
397	- Amyntas II.
392	- Argæus II the Tyrant.
390	- Amyntas II. restored.
371	- Alexander II.
370	- Ptolemy <i>Alorites</i> .
366	- Perdiccas III.
360	- Philip II. son of Amyntas.
336	- Alexander III. called the Great.
323	- Philip III. <i>Arideus</i> .
316	- Cassander.
298	- Antipater.
297	- Alexander.
294	- Demetrius <i>Poliocertes</i> .
287	- Pyrrhus.
286	- Lyfimachus.
280	- Ptolemy <i>Ceraunus</i> .
279	- Meleager.
278	- Antipater the <i>Etesian</i> .
277	- Antigonus, called <i>Gonatas</i> .
243	- Demetrius II.
232	- Antigonus <i>Dofon</i> .
221	- Philip V.
179	- Perseus.
168	- Perseus defeated at the battle of Pydna, and taken prisoner by the Romans, which properly finishes the kingdom of Macedon.
152	- Andriceus, pretending to be the son of Perseus, assumed the tyranny of Macedon, but died in the year 148 B.C.

In the preceding reigns no very interesting event occurred, till that of Amyntas, to whom Megabyzus, the Persian

general, sent seven of the principal commanders of his army to require him to acknowledge king Darius. Amyntas complied, and gave them a magnificent feast. Being intoxicated with wine, they desired that the women might be produced according to the custom of Persia. In this particular they were also gratified; but as their intoxication increased, they began to behave in a brutal manner, and were all slain by the contrivance of Alexander, the son of Amyntas. Upon this Bubaris was sent by Megabyzus, with a considerable body of troops, to revenge their deaths; but Alexander contrived to pacify Bubaris, by introducing to him Gygea his sister, who was a very beautiful woman; and who so far captivated the officer, that for the sake of obtaining her for a wife, he adjusted all things to the satisfaction of Amyntas. From this time the kings of Macedon became tributary to the Persian emperors; but they were always regarded as faithful allies, and treated with kindness and respect. From this reign the history of the kings of Macedonia begins to be blended with that of the other powers of Greece. The Macedonian sovereigns indubitably extended their possessions and authority both to the east and west of their country; and the prudence of Perdiccas I. paved the way for the prosperous reign of Philip II., and for the succeeding conquests of his son Alexander. (See the biographical articles of PHILIP and ALEXANDER *the Great*.) After a reign of about 12 years, the extensive dominions of Alexander were divided among his generals; Philip Aridaus was recognized as his successor; but the ambition of the other princes deprived him of a great part of his father's possessions. His successors, after many destructive wars with the princes who reigned in Asia, terminated their career by a war with the Romans, which proved disastrous to them; so that Perseus, after his defeat, was carried captive to Rome; and in a short time Macedonia became a part of the Roman empire. See the next article.

MACEDONIA *Salutaris*. When Paulus Æmilius had finished the conquest of Macedonia, by his victory over Perseus its last king, he divided this kingdom into four distinct regions, which became subject to different sorts of government, sometimes at the will of the emperor, and at other times under the authority of the senate. At length, after the reign of Constantine, Macedonia became subject to the government of the prætorian prefect of the Eastern Illyria, and was divided into two provinces. The second of these provinces was named *Salutaris*, on account of its mineral waters; it extended itself to the upper part of Macedonia, in the vicinity of the mountains which separated this province from *Mæsia Superior* or *Dardania*. It was under the metropolis of Sobi, and comprised eight towns. Pliny.

MACEDONIA, in *Modern Geography*, a province of European Turkey, bounded on the N. by Servia, on the E. by Romania, on the S. by Thessaly and the Archipelago, and on the W. by Albania. Its figure is irregular; its situation advantageous; and the air clear, sharp, and salubrious. The soil is, in general, fertile; and the maritime coasts particularly abound with corn, wine, and oil. In the inland parts are several uninhabited wadies. It had formerly mines and plenty of timber. Its numerous fine bays render it convenient for trade. Its capital is Salonichi. See the article **MACEDONIA**.

MACEDONIAN KINGDOM, in *Ancient History*, one of the four kingdoms into which the empire of Alexander was divided after his death. This kingdom, under Perseus, who was overcome and taken by Æmilius, and carried in triumph to Rome, where he died in prison, was reduced to the

the form of a Roman province. The other three, *viz.* the Asiatic, Syrian, and Egyptian kingdoms, flourished for a considerable time under their own kings, but were at last compelled to receive the Roman yoke.

MACEONIAN *Parphy*, in *Gardening*. See BERON.

MACEONIAN *Year*. See YEAR.

MACEONIAN, in *Ecclesiastical History*, the followers of Maceonius, bishop of Constantinople, who, through the influence of the Eusebians, was deposed by the council of Constantinople in 362, and sent into exile. He considered the Holy Ghost as a divine energy diffused throughout the universe, and not as a person distinct from the Father and the Son. The sect of Maceonians was crushed before it had arrived at its full maturity, by the council assembled by Theodosius in 381, at Constantinople. See SEMI-ARIANS.

MACEIRA, or MUDJARE, in *Geography*, an island in the Arabian sea, near the coast, about 50 miles long, and from three to eight broad. It is barren and uninhabited, and on the N.W. coast are dangerous shoals, extending 90 miles along the shore, and far into the sea, so that the land cannot be seen till the unskillful pilot touches the rocks. N. lat. 20° 48'. E. long. 57° 35'.

MACEIRA, *Linde*, an island in the Arabian sea, 16 miles long and three broad; 10 miles W. of Maceira.

MACER, *Equitatus*, in *Biography*, a Roman poet, who flourished in the age and reign of Augustus, and is mentioned as a writer in natural history. His works are referred to by Ovid, particularly a poem on the events of the Trojan war, after the period at which Homer concludes. A poem, "De Herbarum Virtutibus," extant under the name of Macer, is now given up as supposititious.

MACER, in *Geography*, a river of Africa, in the country of Tripoli, which runs into the Mediterranean.

MACER, in the *Materia Medica*. The Grecian macer is brought from Barbary; and the part in use is the thick yellow bark, which has a very astringent taste, and is said by Dioscorides to be good against spitting of blood, the dysentery, and fluxes. See SIMAROUBA.

MACERATA, in *Geography*, a town of Naples, in Lavara, about three miles from Capua. Also, a town in the marquise of Ancona, on the Chienta, the see of a bishop, suffragan of Fermo; containing several churches, 13 convents, an university, two academies, and about 10,000 inhabitants; 20 miles S. of Ancona. N. lat. 43° 15'. E. long. 13° 31'.—Also, a town in the duchy of Urbino; 10 miles N.W. of Urbino. N. lat. 43° 48'. E. long. 12° 35'.

MACERATION, in *Pharmacy*, the operation of dissolving a solid body by means of water, or some other liquor.

In this sense, the word amounts to much the same with liquefaction, or liquation.

MACERATION is also used for the infusing of a body in any menstruous fluid, or in order to a solution of its principles, whether with or without fire.

In which sense maceration amounts to much the same with digestion.

Others restrain maceration to that particular kind of digestion which is performed in thick substances, as when having mixed robs with fat to make *unguent. resosum*, the mixture is exposed for some days to the sun, that the virtue of the robs may be the better communicated to the fat.

MACHA MONA, a kind of African calabash. It is the fruit of a very large tree which grows in Africa, and the American islands. When this fruit is ripe, the pulp has a

fourish taste, with a little astringency: it is delicious in hot countries; and they prepare a liquor of it, which they use instead of lemonade, to cool and refresh themselves, and give it to sick persons under a loofeness. The pulp, dried, tastes as well as the spiced bread of Rheims. The slaves make a kind of thick gruel with this pulp and water; it is of an absorbent quality. The African women use the pulp instead of rennet, for curdling their milk.

The seeds of this fruit are as big as small pine-apple kernels, kidney-shaped, of a chestnut-colour, and enclosing an almond far more delicious than our sweet almonds.

MACHACA, in *Geography*, a town of Peru, in the diocese of La Paz; 80 miles S.W. of La Paz. S. lat. 17° 45'. W. long. 69° 14'.

MACHÆRINA, in *Botany*, Vahl. Enum. v. 2. 238. See SENOPIUS.

MACHÆRION, a word used by chirurgical writers, as the name of an instrument of the nature of the incision knife. It is also sometimes used to express an incision; and by the auspices of old it was applied to some particular part of the liver of animals, from which they prefaged events.

MACHÆRUS, or MACHERONTE, in *Ancient Geography*, a city and fort beyond Jordan, in the tribe of Reuben, N. and E. of the lake Asphaltites, two or three leagues from Jordan, and not far from its mouth in the Dead sea. This castle had been fortified by the Amoneans. Gabinius demolished it, and Aristobulus fortified it anew; and Herod the Great made great additions to its strength. At or near it was a spring of very salutary hot waters. John the Baptist was put in prison, and beheaded at Machærus, by the order of Herod Antipas. Josephus Ant.

MACHALA, in *Geography*, a town of South America, in the audience of Quito, and jurisdiction of Guayaquil; annexed to the lieutenantancy of Puna. It lies on the coast of Tumbez, together with that of Naranjol, the landing-place of the river of the same name, called also the Suyá, near which is a road leading to the jurisdictions of Cuenca and Alauli. The jurisdictions of Machala and Manaranjol produce great quantities of cacao, and that of the former is esteemed the best in Guayaquil. In its neighbourhood, as well as in the island of Puna, are great numbers of mangrove-trees; in the wood of which the Indians pay their annual tribute. This wood is used in ships, &c. and is very durable, as it is subject neither to split nor rot: 55 miles N.N.W. of Loxa. S. lat. 3° 15'. W. long. 79°.

MACHAON, in *Biography*, an illustrious hero and physician, who, with his brother Podalirius, accompanied the Grecian army in the expedition against Troy, and performed great services among the troops. These two persons were deemed the sons of Esculapius; and Machaon appears to have been the elder brother, according to the poet Quintus Calaber, who introduces Podalirius as saying, on the occasion of his death, that "his dear brother had brought him up like a son, after their father was taken into heaven, and had taught him to cure diseases." (Lib. vii. v. 60.) Homer, indeed, mentions Podalirius first, when he names both together; but that seems to have arisen only from the convenience of the verse. *Ἠδὲ δὲ Πόδας ἦν Μάχωνος*. For Machaon appears to have been most highly esteemed by the great officers of the army. It was he who administered to Menelaus, when wounded by Tindarus, first wiping the blood from the wound, and then applying emollient remedies, after the manner of his father. It was Machaon, also, who cured the lameness of Philoctetes, occasioned by dropping an arrow, dipped in the gall of the Lernean Hydra, bequeathed him by Hercules,

Hercules, on his foot. "Tarda Philoctetæ sanavit crura Machaon." Prop. lib. ii.

It appears, too, from the writings of the poets, that Machaon was a brave and active soldier; for he is mentioned as engaged in some of the most dangerous enterprises, with the other celebrated leaders. Homer tells of a wound which he received in the shoulder, in one of the battles of the Trojans; and Virgil and Hyginus inform us, that he was one of the brave warriors who entered the wooden horse, from which, according to the former, he was the first to descend. (Æneid. lib. ii. v. 263. Hygin. Fabul. lib. i. cap. 81. &c.) He is said to have lost his life in single combat with Nereus, or, as others state, with Euryphilus, the son of Telephus, during the siege of Troy; which, however, is inconsistent with the assertion just mentioned, since the siege was terminated by the introduction of the troops in the wooden horse. (See Pausanias in Laconic. 2. Calaber, lib. vi. & vii.) Pausanias adds, that the remains of Machaon were preserved by Nestor, and conveyed to Messenia, where they were buried.

Machaon married Anticlea, daughter of Diocles, king of Messenia, by whom he had two sons, Nicheachus and Gorgastus, who resided at Phæra, and possessed the territory of their grandfather, until the Heraclidæ, on their return from Troy, made themselves masters of Messenia, and the rest of the Peloponnesus. Machaon is supposed to have been a king, either in his own right, or that of his wife, since Homer, in two or three places, calls him "Father of the people," (πατὴρ λαοῦ), a title which he gives to Agamemnon and the other kings. Pausanias mentions three other sons of Machaon, namely, Sphyrus, Alexanor, and Polemocrates, who are supposed to have been the fruit of another marriage. M. Goulin, in his literary and critical memoirs, states his opinion, that the birth of Machaon may be fixed about the year of the world 2765. See Le Clerc. Hist. de la Médecine. Schultzius Hill. Medicinæ.

MACHAU, GUILLAUME, a French poet and musician, born about 1282. He was at first in the service of the count of Philippe-le-Bel, and, in 1307, was appointed valet-de-chambre to the king, and continued to occupy this office to the end of that prince's reign, who died in 1314.

As the works of this author are the most ancient lyric compositions that have been preserved in France, with the original music, great pains have been taken in commenting them, and rendering both words and music intelligible.

The abbé Lebœuf, in the year 1746, gave a very ample and satisfactory account to the Academy of Inscriptions at Paris of two volumes of French and Latin poems, preserved in the library of the Carmelites of that city, "with a description of the kind of music to which some of these poems were set."

In 1747, the count de Caylus, having found in the king of France's library, N. 7600—2, a duplicate of these poems, gave likewise an account of them to the same Academy, in two memoirs. The author, Guillaume de Machau, is styled by the count, *poet and musician*; and both these excellent critics agree, that he flourished about the middle of the fourteenth century, and died in 1372. Among the poems, which are written up in various subjects, there is an infinite number of lurs, virelais, ballads, and rondeaux, chiefly in old French, with a few in Latin, and set to music: some for a single voice, and others in four parts, triplum, tenor, contratenor, and a fourth part, without a name. In these last pieces, as the words are placed only under the *tenor part*, it is natural to conclude that this was the principal melody. In the music, which is written with great care and neatness, notes in a lozenge form, with tails to them, frequently occur; these, whether the heads were *full* or *open*, were at

first called *minims*; but when a still quicker note was thought necessary, the white or open notes only had that title, and the black were by the French called *noirs*, and by English *crabbits*: a name give by the French with more propriety, from the hook or curvature of the tail, to the still more rapid note, which we call a *quaver*.

The Latin poems are chiefly motets, and for a single voice; some of which are written in black and red notes, with this instruction to the singers: "nigra sunt perfectæ, & rubra imperfectæ." An admonition worth remembering by those who wish to decipher music of the fourteenth and fifteenth centuries, in which red notes frequently occur. It was an easy expedient of diminution, till the invention of printing, when the use of ink of different colours, on the same page, occasioned the expence and trouble of *double printing*. The abbé Lebœuf observes, that the diffusion and accelerated motion of notes, during these ages, gave great offence and scandal to pious and sober Christians. In a lyric eleison to the Gregorian chant, which is called *tenor*, the three parts that are added to it are called triplum, motetus, and contratenor. In the second volume of these poems the common chants of the whole mass, and even the credo, are written in four parts. This mass is supposed to have been sung at the coronation of Charles V. king of France, 1364.

There are in the French MS. many ballads and rondaux in three parts, tenor, triplum, and contratenor. The fourteenth century seems the era when music in parts, moving in different melodies, came first into general favour; for of the preceding age no music can be found of more than two parts in strict counterpoint of note against note.

Machau calls his collection of songs set to music, *Remedes de forisme*, regarding music as a specific, or at least an opiate, against the ills of life. In the illuminations to these lyric compositions an assembly of minstrels is represented with thirty or forty musical instruments, of which he gives the names. His poem called "Le Dit de la Harpe," is a moral and allegorical piece in the style of the famous "Roman de la Rose," by Guillaume de Loris, and Jean de Meun.

The abbé Rive has likewise given an historical and critical account of another MS. copy of these poems in the collection of the duke de la Vallière; but none of these gentlemen have produced specimens of Machau's musical compositions; indeed the count de Caylus frankly confesses, that though he has studied this music with the utmost attention, and consulted the most learned musicians, he has been utterly unable to satisfy his curiosity concerning their intrinsic worth.

MACHAU, in *Geography*, a town of Bohemia, in the circle of Königgrätz; eight miles S.W. of Brannaw.

MACHAVANA, a river of Africa, which runs into the Indian Sea, 3. lat. 26. 45.

MACHAULT, JAMES, born in *Britany*, a French Jesuit, was a native of Paris, and born in 1599. He entered on his novitiate in his eighteenth year, and after having finished the usual course of academic studies, he was selected to teach, first pious literature, then philosophy, and for several years disputation, in different seminaries belonging to the order. He was elected successively rector of the colleges at Alençon, Orleans, and Caen, and died in his native city in 1682. He was author of many considerable works, as "The Account of the Missions in Paraguay and other Parts of South America," 8vo. 1650; "A Relation of the State of Affairs in Japan," 1647; "Account of the Provinces of Goa," &c.; "A Relation of the Travels of twenty-five Members of the Society on the Indian Mission," 1659; "Account of the Mission of the Society in Persia," &c.

MACHAULT,

MACHAULT, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Vouziers; nine miles S.W. of Vouziers. The place contains 693, and the canton 4000 inhabitants, on a territory of $242\frac{1}{2}$ kilometres, in 14 communes.

MACHÉCO, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Nantes; 8 miles S.W. of Nantes. The place contains 1899, and the canton 5152 inhabitants, on a territory of 155 kilometres, in six communes. N. lat. 47° . W. long. $1^{\circ} 44'$.

MACHERA LAPIS, in *Natural History*, the name of a stone of a ferruginous colour, frequent on mount Berecynthus in Phrygia. Plutarch, and many other grave writers, relate, that if any person found this stone, and took it up at the time of the celebration of Cybele, he instantly was seized with madness.

MACHERIA, in *Geography*, a town of Hindoostan, in Palnaud; six mile S.W. of Timerycotta. N. lat. $27^{\circ} 35'$. E. long. $77^{\circ} 15'$.

MACHERN, a town of Prussia, in Natangen; 25 miles S. of Rattenburg.

MACHERRY, a town of Hindoostan, in the country of Mewat; 70 miles S.S.W. of Delhi.

MACHESIN, or **MACHISIN**, a town of Asiatic Turkey, in the province of Diarbekir; 105 miles S.E. of Raca.

MACHIA, a town of Naples, in the country of Molise; 12 miles S.W. of Molise.—**Alfo**, a town of Naples, in the Capitanata; 10 miles N.N.W. of Volturara.—**Alfo**, a town of Naples, in Calabria Citra; five miles N. of Bisignano.—**Alfo**, a town of Naples, in Principato Citra, on the coast; 15 miles S. of Capaccio.

MACHIAN, one of the Molucca islands, near the W. coast of Gilolo; about 18 miles in circumference, and populous. The Dutch have three forts garrisoned with soldiers. Its principal articles of commerce are cloves and sago; a little N. of the line. E. long. $127^{\circ} 21'$.

MACHIANA, an island at the mouth of the river of the Amazons, about 15 miles long and three broad; a little S. of the line. W. long. $57^{\circ} 2'$.

MACHIAS, a port of entry, post-town, and seat of justice in Washington county, and state of Maine, America, situated on a bay of the same name; 20 miles S.W. of Passamaquoddy, in N. lat. $47^{\circ} 37'$. This town carries on a considerable trade to Boston and the West Indies, in fish, lumber, &c. It was permanently settled in 1763, and incorporated in 1784. The chief settlements are at the E. and W. Falls, and at Middle river. At W. Falls, there is a gaol, and the county courts are held there. The entrance of Machias river is in N. lat. $44^{\circ} 37'$. W. long. $66^{\circ} 56'$. The town is divided into four districts for the support of schools, and into two for the convenience of public worship. In 1792 Washington academy was established here, which has for its support a township of land. In 1800 the town contained 114 inhabitants. The exports consist principally of lumber, viz. boards, shingles, clap-boards, laths, and various kinds of dressed timber. The cod-fishery, which might be prosecuted to advantage, has been neglected. The saw-mills are 17 in number, and much employed. The total amount of exports annually exceeds 15,000 dollars. From Machias bay to the mouth of St. Croix there are many fine islands. Morfe.

MACHIAVELISM, in *Literary History*, is a species of detestable politics, which may be defined in few words, the art of reigning tyrannically, the principles of which are inculcated in the works of Machiavel, a native of Florence, and particularly in his treatise, entitled "The Prince." M. de

Wicquefort observes, concerning the character of this writer; Machiavel says almost every where what princes do, and not what they ought to do. To the same purpose the chancellor Bacon remarks: "Est quod gratias agamus Macchiavello et hujus modi scriptoribus qui aperte & indissimulante professunt quid homines facere soleant non quid debeant." Machiavel was secretary, and afterwards historiographer to the republic at Florence. He was put to the rack upon the suspicion of being concerned in a confederacy against the house of Medicis; but he endured the torments of it, without making any confession. He was as much an enemy to religion as to sound politics; and is said to have died in the year 1530, uttering profane jests and blasphemies. Bayle. See **MACCHIAVELLI**.

MACHIAWARA, in *Geography, a town of Hindoostan, in the circar of Sirhind; 28 miles N. of Sirhind.*

MACHICOLATION, from *mecke*, a match or wick to preserve fire, and *coulr*, to flow, in *Fortification*, perpendicular apertures in the upper part of the gate of an ancient castle, for the purpose of pouring down various burning substances on the assailants, when they were battering them, or otherwise trying to force them open. In various ancient charters, permission was granted to the owners of castles, *embattelandi, kernellandi, and machicolandi*.

MACHICORA, in *Geography*, a river of Madagascar, which gives name to a province, and runs into the sea on the S. coast. S. lat. $25^{\circ} 5'$. E. long. $41^{\circ} 12'$.

MACHIGASTA, a town of South America, in the province of Tucuman; 50 miles W.S.W. of St. Fernando.

MACHINE, in a general sense, signifies any thing that is used to augment or to regulate moving forces or powers; or, it is any instrument employed to produce motion, so as to save either time or force. The word is derived from *unxars, machine, invention, art*; and is therefore properly applied to any agent in which these are combined, whatever may be the strength or solidity of the materials of which it is composed. The term machine, however, is by common usage generally restricted to a certain class of agents, which seem to hold a middle place between the most simple *organa*, commonly called tools or instruments, and the more complicated and powerful, termed *engines*. This distinction, however, does not enter into the present article; we shall consider machines under two heads, *simple* and *compound*. To the first class belong the *lever*, the *inclined plane*, the *screw*, the *wedge*, the *wheel* and *axle*, and the *pulley*, commonly called the six mechanical powers; though some authors will only allow the lever, and the inclined plane, to be simple machines, the others being compounded of those two.

Compound machines are all such as consist of a combination of the several simple machines or mechanical powers above-mentioned, the number of which in the present advanced state of the sciences is almost infinite. These are again classed under different denominations, according to the agents by which they are put in motion, the purposes they are intended to effect, or the art in which they are employed, as hydraulic, pneumatic, military, architectural, &c. machines. The ancients excelled in the two latter species of engines, but in those which relate to civil arts and manufactory, the moderns have doubtless far exceeded their masters. With regard to military machines, the invention of gunpowder has completely changed their nature, and all those of the ancients are become useless and forgotten; these were principally of three distinct species, viz. those employed for throwing destructive weapons; as the *scorpion*, which was for casting arrows; the *catapulta* for stones and javelins; the *pyrobale* for flaming darts; the *ballista* for bullets, &c. &c.

Others

Others were for razing the walls of fortified places, of which the principal was the *aries*, or *battering ram*; and those of the third kind were for covering the approaches of the besiegers, as the wooden tower, &c.; for a description of which see the respective articles. The warlike machines employed by Archimedes in the defence of Syracuse have been much applauded by the ancients, and though many of the circumstances related on this head are doubtless false or exaggerated, yet it is sufficient to know the genius of their author to be convinced that they were powerful and effective, probably much exceeding any of those of which the construction has been ascertained.

Of the architectural machines of the ancients we are totally unacquainted, and one is at a loss to conceive what means they employed for transporting and raising those enormous stones which are found in the walls of some ancient buildings, though it is not unlikely that they owed as much to their patient perseverance and manual labour, as to the power of their machines. The Spaniards, when they made the conquest of Peru, were struck with astonishment to find the natives, whom they considered as savages and barbarians, raising enormous masses of stone of ten feet square for building walls and other purposes, without the assistance of any instruments than those which nature had supplied them with; unacquainted with any other scaffolding but that of banks of earth raised against their buildings, they contrived by strength of hand to raise these massy loads up the inclined planes thus formed; and many of the Druidical remains in this country were probably erected in a similar manner. The ancient Greek and Roman architects, however, were no doubt acquainted with, and employed very powerful machines in the construction of their noble edifices, with the nature of which we have not been informed; even Vitruvius, who writes expressly on the subject, has left us nothing that can throw any light on the construction of these engines, yet that they were in possession of immense and wonderful machinery, appears in the most convincing manner to any person who reflects on the magnificent structures which they erected, and which excite to this day the wonder and admiration of the world, not only on account of their grandeur and incomparable elegance, but also on account of the mechanical knowledge that seems indispensably necessary for their erection.

The hydraulic machines of the ancients were indeed much inferior to those of modern invention. The *sereno* of Archimedes, and the *pumps* of Ctesibius, were the principal engines of this description; for which see the respective articles. As to the modern machines they are too numerous to admit even of a slight enumeration in this place; most of them, however, of any importance, will be found under the several heads in this work. See CRANES, *Wind* and *Water MILLS*, *STEAM Engine*, &c. &c.

Montucla, at the conclusion of the third volume of his "Histoire des Mathématiques," has given a catalogue of several interesting works, which have been compiled in order to describe and exhibit the most important and curious machines, both ancient and modern, of which we have selected a few for the information of those who may not possess the above-mentioned work.

1. The first and most interesting modern work of this description is entitled "Le diverse et artificieuse machine del capitano Agostino Ramelli dal ponte della Trebia, &c. &c. composta in lingua Italiana et Francese; a Parigi 1588," in folio, (in Germany,) in 1620. This is a very scarce work, seldom to be met with but in choice libraries.

2. "Machine nova Pauli Verantii cum declaratione, La- Vol. XXI.

tinia, Italica, Hispanica, Gallica, et Germanica," Venetiis 1591, 1625, in folio, with figures.

3. "Résumé de plusieurs Machines militaires, &c. pour la Guerre et Récréations," par François Thypourel et Jean Appus, 1620, 4to.

4. "Heinrich Zeizings, Theatrum machinarum," Lipsie 1621.

5. "A Century of Inventions, &c." by Edward Somerfet, marquis of Worcester, London 1663, in 12mo.

6. "Les dix Livres d'Architecture de Vitruve, &c." translated into French by Claude Perrault, 1673, folio.

7. "Veterum mathematice, Astronomicæ, Apollodori, &c." 1693, folio. This learned and curious edition of the ancient Greek machinicians was begun by Thaveret, and finished by La Hire; but it relates principally to military engines.

8. "Theatrum machinarum universale, &c." by Jacob Leupold, Lipsie, seven volumes folio, 1724, 1727, 1774. This is the greatest and most complete work of the kind that ever was published. The first volume is little more than an introduction to the work; the second and third volumes contain descriptions of hydraulic machines; the next two volumes relate to machines for raising weights, the theory of levelling, and other subjects; and the sixth treats principally on machines connected with the construction of bridges; the seventh volume is entitled "Théâtre arithmétique géométrique," where the author treats of all instruments employed in these two sciences. This work would have been much more considerable, if its author had lived to complete the immense task he had undertaken.

9. "A short Account of the Methods made use of in laying of the Foundation of the Piers of Westminster Bridge," by Charles Labelye, 1739.

10. "The Advancement of Arts, Manufactures, and Commerce; or, A Description of useful Machines and Models," by A. M. Baily, London 1778, 1779, folio.

Besides the above-mentioned works, many useful particulars may be gathered from Strada, Besson, Beroaldus, Bockles, Beyer, Lempergh, Van Zyl, Belidor's Architecture hydraulique, Desaguliers's Course of experimental Philosophy, Emerson's Mechanics. The Royal Academy of Sciences at Paris have also given a collection of machines and inventions approved of by them. This work, published by M. Gallon, consists of six volumes in quarto, containing engraved representations of the machines, with their descriptions annexed.

We might have carried the enumeration of works of this kind to a much greater length, but the above are the most interesting, and the reader who wishes for farther information on this subject may consult the history of Montucla above-mentioned. But we ought not to omit to mention in this place, the second volume of the "Architecture Hydraulique" of Prony, and the second volume of Gregory's Mechanics: the first of these relates principally to steam engines, but the latter contains a description of the most useful modern machines for various purposes.

In the construction of machinery, as also in estimating its effects, several important considerations naturally arise in the mind of a skilful artist, such as the effect of FRICTION, RIGIDITY of ropes, the STRENGTH and STRESS of materials; the proper measure, comparison, and equilibrium of FORCES, the laws of ROTATORY and ACCELERATED motion, &c. &c. These are all treated of under the respective articles in the Cyclopædia, and it therefore only remains for us in this place to offer a few remarks on the nature of machines in general, and the best means of determining their maximum effects.

Machines are introduced for three purposes, viz. to accommodate

commutate the direction of the moving force to that of the resistance : to be overcome : to increase the effect of a given finite power, so as to overcome a resistance which is greater, and would otherwise ever remain unchanged : and lastly, to regulate and modify a variable force, so as to produce a constant and uniform effect. These are the principal ends to be accomplished by machines, and the experienced engineer will always endeavour to execute them in the simplest manner possible; for complicated machinery is not only most liable to inaccurate adjustment, and frequent disarrangement, but is likewise more cumbersome and expensive, at the same time that the retardation arising from friction, adhesion, and inertia, is more considerable, and consequently a greater power becomes necessary, in order to produce the same effect. Another important point to be attended to, is the most advantageous application of the first mover, whether this agent be air, water, steam, or animal strength. To enter upon this question in all its generality, would far exceed our limits; besides, with regard to the three former, they will be better investigated under the articles *Wind* and *Water Mills*, *STEAM Engines*, &c.; what few remarks, therefore, we have to make on this head, will be confined to the application of animal exertion to the motion of machines, and for the other agents we must refer the reader to the articles above-mentioned.

We have a striking instance of the injudicious application of the exertion of men, in the old crane worked by means of an internal walking wheel, which, from its nature, must be very heavy, while the action of the man is exerted at a very trifling distance from the axle, and consequently at a great mechanical disadvantage; whereas in Hardie's crane, the man acting externally at the greatest distance from the fulcrum, produces a much greater effect with less expence of labour; the other advantages which this machine possesses over the one above-mentioned, not arising solely from this cause, are not connected with our present enquiry.

The above remark applies principally to the mechanical advantage to be obtained in the application of a first mover; but there is also another consideration of a physical nature, which is equally important, and ought therefore to be particularly attended to. No animal can exert more than a determinate and limited force; and, consequently, if it requires all this force merely to produce an equilibrium, no effect will result from the action; and, on the other hand, if all the strength of a man or horse is employed in giving motion to himself, or to external objects before the application reaches the resistance, there is still the same unproductive effect. A man, for example, pushing at a capstan bar, must first of all walk as fast as the bar moves round, which evidently requires an expenditure of his muscular power; but this alone will not render his exertion effective: he must also press the bar forward, with as much force as he has remaining above that which he expended in walking at that rate. The proportion of these two expenditures may be very different under different circumstances; and on the judicious selection of such circumstances as make the first of these as small as possible, lies much of the skill of the engineer. In the common operation of thrashing corn, much more than half the man's power is expended in giving the necessary motion to his own body; and only the remainder is employed in urging forward the swingle which is in motion, sufficient for shaking out the ripe grain from the stalk. Dr. Robison mentions an experiment, made in order to ascertain the quantity of power thus lost. In order to which, the swingle was taken off the flail, and the same weight or load put on the end of the staff; then by causing the labourer to perform the usual motions of thrashing, with all the rapidity

that he could continue during the ordinary hours of work; it was found that the number of motions thus made was to those made in the actual operation of thrashing, in about the ratio of 5 to 2: whence we may infer, that at least half the thrasher's power is expended in merely moving his own body. We may also bring another very simple case, by way of further illustration. Suppose a quantity of earth is to be removed from one place to another by barrows. It is obvious that the loads may be so great, that a man must exert his whole strength barely to lift up the shafts, and consequently will have none left to push the barrow forward: if part of the load be taken off, he can go forward, and so much the faster as the quantity of the load is reduced; but if even the whole be taken away, he can still only move at a certain rate, and, consequently, in neither of the extreme cases is any effect produced. It becomes then an interesting question to determine what load he ought to carry, in order to produce the greatest possible effect in a given time. We shall not, in this place, enter any farther upon this subject, trusting that what has been already advanced will be sufficient to point out the necessity of attending to such circumstances; and in the subsequent part of the present article, we will endeavour to explain in what manner the proper adjustment of power and effect may be computed.

The nature of the first movement being determined, the next object is to communicate it to the desired point, where the resistance is to be overcome; and much of an artist's skill depends upon performing this in the simplest and most effectual manner possible. In order to this, it frequently becomes necessary to convert one species of motion into another species: as, for example, a rotatory into a reciprocating motion, or a reciprocating into a rotatory motion, &c. &c. The methods of forming this communication are extremely numerous, and it will not therefore be expected that we should attempt an enumeration of them. In some instances, a simple lever or resilient cord will answer better than any combination; in others, it is highly advantageous to use a combination of levers acting upon each other by means of so many fulcra, and by which the direction of the motion may be changed at pleasure; in others, as when motion is communicated to a series of wheels and axles in succession, it may be effected by a rope running in grooves round one wheel and the succeeding axle, or by means of tooth and pinion work, by a barrel and endless screw, and various other contrivances which will naturally suggest themselves, according to the circumstances under which they arise.

This part of the construction being settled, other important circumstances require particular attention, *viz.* to adjust the several parts of the machine so, that its motion may be easy, free, and uniform. One of the most obvious methods of rendering a motion uniform is by means of a *pendulum* and *escapement* (see these two articles); and where these cannot conveniently apply, a fly is sometimes employed; for a particular description of which, see *FLY*. The uniformity of a machine is not, however, wholly dependent upon the application of such regulators: there are other points connected with this subject, that must not be overlooked, and on which we intend to offer a few remarks: consulting ourselves, for this purpose, of the observations of Dr. Robison. When heavy flumpers are to be raised, in order to drop on the matters to be pounded, the wipers by which they are lifted should be made of such a form, that the flumper may be raised by a uniform pressure, or with a motion almost perfectly uniform: if this is not attended to, and the wiper is merely a pin sticking out from the axle, the flumper is forced into action at once, which occasions violent jolts

jolts to the machine, and great strains on its moving parts, and their points of support; whereas, when they are gradually lifted, the inequality of the motion is never felt at that point of the machine where the power is applied. We have seen, says the professor, pistons moved by means of a double rack on the piston rod, where a half wheel takes hold of one rack, and raises it to the required height; and the moment the half wheel has quitted that side of the rack, it lays hold of the other side, and forces the piston down again. This was considered as an improvement of the common method of the crank, by correcting the unequal motion of the piston. But in fact it is far inferior to the latter, as it occasions such abrupt changes of motion, that the machine is shaken and torn to pieces with the jolts it occasions; a circumstance which will always be avoided as much as possible by a judicious engineer.

When several stampers, pistons, or other reciprocal movers, are to be raised and depressed, their times of action ought to be distributed in a uniform manner, so that the machine may always be equally loaded with work. When this is done, and the observations in the preceding paragraph attended to, the machine may be made to move almost as smoothly as if there were no reciprocations on it. Nothing shews the ingenuity of the constructor more than the artful, yet simple, contrivances for obviating those difficulties that unavoidably arise from the very nature of the work that must be performed by the machine, and of the power employed. We mentioned above, the conversion of the continued rotation of an axis into the reciprocating motion of a piston, and the improvement that was thought to have been made in the common and obvious contrivance of the crank, but which, as was observed, occasioned such jolts as would in a short time have destroyed the machine. In order to avoid this, in a large forge where a great sledge hammer of seven hundred weight was to be raised, the engineer formed the wipers into spirals, which communicated motion to the hammer almost without any jolt whatever: and under some circumstances, this contrivance would have been highly beneficial; but in the machine to which we allude, it would not apply, as it did not communicate a sufficient momentum to the hammer in its descent: yet it is deserving of notice, as it might in some cases become extremely advantageous.

In employing a power, which of necessity reciprocates, to drive machinery, in which a rotatory motion is required, as in applying the steam-engine to a cotton or grist-mill, considerable difficulties also arise, which must be attended to with particular care. The necessity of reciprocation on the first mover wastes much power, because the instrument that communicates such immense force must be extremely strong, and well supported. The impelling power is wasted in imparting, and afterwards destroying, a great quantity of motion in the working beam. The skilful engineer will attend to this, and do his utmost to procure the necessary strength of the first mover, without making it a vast load of inert matter: he will also remark that all the strains on it, and on its supports, are changing their direction on every stroke; which therefore requires particular attention in the manner of supporting it. If we observe steam-engines that have been long erected, we shall find that they have uniformly shaken the building to pieces, which is principally to be attributed to the inattention of the engineer to this circumstance; and experience has now taught us, that no building can long withstand the desultory and opposite jolts of such immense masses; and, consequently, that the great movements ought to be supported by a frame-work, independent of the building which contains it. Another cir-

cumstance, on which the uniformity of the motion depends, is the form given to the teeth of the wheel: this is of great importance, and has excited great attention amongst both theoretical and practical mechanicians. Two forms have been proposed: of these the first was given by La Hire, who affirmed that the pressure would be uniform, if the teeth were formed into cycloids; and M. Camus, in his "Cours de Mathematique," has adopted and perfected La Hire's principle, and applied it to the various cases that are likely to arise in practice. The construction, however, is liable to a limitation; on which account, a second method has been proposed, which secures the perfect uniformity of motion, without any such limitation. This consists of making both teeth portions of involutes of circles; but as we shall consider this subject under the articles *Tooth* and *Piston Work*, it will be useless to insist any farther upon it in this place; and we will therefore proceed to the theoretical investigation of the power of machines, and their maximum effect: limiting our observation to those principally whose motion is uniform, these forming by far the most numerous class, and the knowledge of which is, therefore, of the greatest importance.

Of the maximum Effects of Machines.—When forces acting in contrary directions, or in any such directions as produce contrary effects, there is with respect to every simple machine, and consequently with respect to every compound one, a certain relation between the powers and the distances at which they act, which, if subsisting in any such machine when at rest, will preserve it in that state of statical equilibrium; because the efforts of these powers, when thus related with regard to magnitude and distance, being equal and opposite, destroy each other, and have no tendency to change the state of the system to which they are applied. So also, if the same machine have been put into a state of uniform motion, whether rectilinear or rotatory, by the action of any power distinct from those we are now considering, and these two powers be made to act upon the machine in such motion, in a similar manner to that in which they act upon it when at rest, their simultaneous action will preserve it in that state of uniform motion, or dynamical equilibrium, and this for the same reason as before; because their contrary effects destroy each other, and have, therefore, no tendency to change the state of the machine. But if at the time a machine is in a state of balanced rest, any one of the opposite forces be increased, while it continues to act at the same distance, this excess of force will disturb the statical equilibrium, and produce motion in the machine; and if the same excess of force continues to act in the same manner, it will, like every constant force, produce an accelerated motion: or if it should undergo particular modifications, when the machine is in different positions, it may occasion such variations as will render it alternately accelerated and retarded. Or, the different forces of resistance to which a moving machine is subjected, as the rigidity of cords, friction, resistance of the air, &c. may so modify it, as to change a regular or irregular variable motion into one which is uniform. Hence, then, the motion of machines may be considered as of three kinds, as that which is gradually accelerated, which obtains commonly in the first instants of the communication; 2. That which is entirely uniform. 3. That which is alternately accelerated and retarded. Pendulum clocks and machines that are moved by a balance are related to the third class. Most other machines are of the second class, at least a short time after their motion is commenced.

Now, although the motion of a machine be alternately accelerated and retarded, it may, notwithstanding, be mod-

ured by an uniform motion, in consequence of the periodical and regular repetition which may exist in the acceleration and retardation. Thus, the motion of a second pendulum, considered in relation to a single oscillation, is accelerated during the first half second, and retarded during the second; but the same motion taken for many oscillations may be considered as uniform. Suppose, for example, that the extent of each oscillation is five inches, and that the pendulum has made ten oscillations; its total effect will be to have run over 50 inches in 10 seconds, and as the space described in each second is the same, we may compare the effects to a moveable, which moves for 10 seconds at the rate of five inches per second. We see, therefore, that the theory of machines, whose motions are uniform, conduces naturally to the estimation of the effects of those whose motion is alternately accelerated and retarded, so that what follows will be directed to those machines only, whose motion falls under the second head, such problems being of far the greatest utility in practice.

We have had already frequent occasion to make use of the terms *moving*, or *moving force* and *resistance*; and in what follows, they will be used in the same general sense. By the first is always to be understood any cause of motion whatever, and by the latter, any thing that is opposed to the action of the former. The *impelled point* of a machine, is that to which the action of the moving power may be considered as immediately applied; and the *working point* is that where the resistance arising from the work to be performed immediately acts, or to which it ought all to be reduced. Thus in the wheel and axle, *Plate I. fig. 6. Mechanics*, where the moving power P is to overcome the weight or resistance W, by the application of the cord to the wheel and to the axle, A is the impelled point, and E the working point. The *velocity of the moving power* is the same as the velocity of the impelled point; and the *velocity of the resistance*, the same as that of the working point. The *performance* or *effect* of a machine, or the *work done*, is measured by the product of the resistance into the velocity of the working point; and the *momentum of impulse* is measured by the product of the moving force into the velocity of the impelled point.

These definitions being established, we may exhibit a few of the most useful problems relative to the effect of machines, and with which we must conclude this article.

Let A B (*Plate XXXII. Mechanics. fig. 1.*) represent the velocity of a stream, A C the velocity of the part of the engine which it strikes, when the motion of the machine becomes uniform, and C B will represent their relative velocity, upon which the effect of the engine depends. It is known that the action of a fluid upon a given plane, is as the square of this relative velocity; consequently the weight raised by the engine, when its motion becomes uniform, being equal to this action, it is likewise as the square of C B. Let this be multiplied by A C, the velocity of the part of the engine, impelled by the fluid; and the effect of the engine in a given time will be proportional to $A C \times C B^2 =$ (supposing C B to be bisected in D) $A C \times 2 C D \times 2 D B = 4 A C \times C D \times D B$; consequently, the effect of the engine is greatest when the product of A C, C D, and D B is greatest. But it is easy to see, that this product is greatest when the parts A C, C D, and D B, are equal; for if you describe a semicircle upon A D, and the perpendicular C E meet the circle in E, then $A C \times C D = C E^2$, and is greatest when C is the centre of the circle; D that in order that $A D \times C D \times D B$ may be the greatest possible, A D must be bisected in C; and C B having been bisected in D, it follows

that A C, C D, D B, must be equal; or that A C, the velocity of the part of the engine impelled by the stream, ought to be but one-third of A B, the velocity of the stream. In this case, when, (abstracting from friction) the engine acts with the utmost advantage; the weight raised by it is to the weight that would just sustain the force of the stream, as the square of C B, the relative velocity of the engine and stream, to the square of A B, which would be the relative velocity, if the engine was quiescent; that is, as 2×2 to 3×3 , or 4 to 9. Therefore, that the engine may have the greatest effect possible, it ought to be loaded with no more than $\frac{4}{9}$ th of the weight, which is just able to sustain the efforts of the stream. See Maclaurin's Account of Sir Isaac Newton's Discoveries, p. 171, and Fluxions, art. 928.

Again, suppose that a given weight P, (*fig. 2.*) descending by its gravity in the vertical line, raises a greater weight W, likewise given, by the rope P M W, that passes over the fixed pulley M) along the inclined plane B D, the height of which B A is given; and let it be required to find the position of this plane, along which W will be raised in the least time, from the horizontal line A D to B. Let B C be the plane upon which, if W was placed, it would be exactly sustained by P; in which case, P is to W as A B to B C. But W is to the force with which it tends to descend along the plane B D, as B D to A B; consequently the weight P is to that force, as B D to B C. Therefore the excess of P above that force (which excess is the power that accelerates the motion of P and W) is to P, as $B D - B C$ to B D; or taking B H upon B C equal to B D, as C H to B D. But it is known that the spaces described by motions uniformly accelerated, are in the compound ratio of the forces which produce them and the squares of the times; or, that the square of the time is directly as the space described in that time, and inversely as the force; consequently, the square of the time in which B D is described by W, will be directly as B D, and inversely as $\frac{C H}{B D}$, and will be least when $\frac{B D^2}{C H}$ is a minimum; that is, when $\frac{B C^2}{C H} + C H + 2 B C$, or (because

$2 B C$ is invariable) when $\frac{B C^2}{C H} + C H$, is a minimum.

Now as when the sum of two quantities is given, their product is a maximum when they are equal to each other; so it is manifest, that, when their product is given, their sum must be a minimum when they are equal. Thus it is evident, that as in *fig. 1*, the rectangle or product of the equal parts A C and C D was equal to C E²; so the rectangle of any two unequal parts, into which A D may be divided, is less than C E², and A D is the least sum of any two quantities, the product of which is equal to C E². But

the product of $\frac{B C^2}{C H}$ and C H is $B C^2$, and consequently,

given: therefore the sum of $\frac{B C^2}{C H}$ and C H is least when

these parts are equal, that is, when C H is equal to B C, or B D equal to $2 B C$. It appears, therefore, that when the power P and weight W are given, and W is to be raised by an inclined plane, from the level of a given point A to the given point B in the least time possible; we are first to find the plane B C, upon which W would be sustained by P, and to take the plane B D double in length of the plane B C; or we are to make use of the plane B D, upon which

a weight

a weight that is double of W could be sustained by the power P .

For another example; suppose a fluid, moving with the velocity and direction AC , (*fig. 3.*) strike the plane CE ; and suppose that this plane moves parallel to itself in the direction CB , perpendicular to CA , or that it cannot move in any other direction. Then let it be required to find the most advantageous position of the plane CE , that it may receive the greatest impulse from the action of the fluid. Let AP be perpendicular to CE in P , draw AK parallel to CB , and let PK be perpendicular upon it in K , and AK will measure the force with which any particle of the fluid impels the plane CE in the direction CB . For the force of any such particle being represented by AC , let this force be resolved into AQ , parallel to EC , and AP perpendicular to it; and it is manifest, that the latter AP only has any effect upon the plane CE . Let this force AP be resolved into the force AL perpendicular to CB , and the force AK parallel to it; then it is manifest, that the former, AL , has no effect in promoting the motion of the plane in the direction CB ; but that the latter AK , only, measures the effort by which the particle promotes the motion of the plane CE in the direction CB . Let EM and EN be perpendicular to CA and CB , in M and N ; and the number of particles, moving with directions parallel to AC , incident upon the plane CE , will be as EM . Therefore the effort of the fluid upon CE being as the force of each particle, and the number of particles together, it will be as $AK \times EM$; or, because AK is to AP ($= EM$) as EN to CE , as $\frac{EM^2 \times EN}{CE}$;

so that CE being given, the problem is reduced to this, to find when $EM^2 \times EN$ is the greatest possible, or a maximum. But because the sum of EM and of EN ($= CM$) is given, being always equal to CE , it follows that $EN^2 \times EM$ is greatest when $EN^2 = \frac{1}{2} CE$; in the same manner as it was demonstrated above, that when the sum of AC and CB (*fig. 1.*) was given, $AC \times CB$ was greatest, when $AC = \frac{1}{2} AB$. But when $EN^2 \times EM$ is greatest, its square root $EN \times EM$ is of necessity at the same time greatest. Therefore the action of the fluid upon the plane CE , in the direction CB , is greatest when $EN = \frac{1}{2} CE$, and consequently $EM = \frac{1}{2} CE$; that is, when EM , the sine of the angle ACE , in which the stream strikes the plane, is to the radius, as the $\sqrt{2}$ to $\sqrt{3}$; in which case it easily appears, from the trigonometrical tables, that this angle is of $54^\circ 44'$.

Several useful problems in mechanics may be resolved by what was shewn in the preceding paragraph. If we represent the velocity of the wind by AC , a section of the sail of a windmill, perpendicular to its length by CE , as it follows from the nature of the engine, that its axis ought to be turned directly towards the wind, and the sail can only move in a direction perpendicular to the axis, it appears, that when the motion begins, the wind will have the greatest effect to produce this motion, when the angle ACE , in which the wind strikes the sail, is of $54^\circ 44'$. In the same manner, if CB represent the direction of the motion of a ship, or the position of her keel, abstracting from her leeway, and AC be the direction of the wind, perpendicular to her way, then the most advantageous position of the sail CE , to promote her motion in the direction CB , is when the angle ACE , in which the wind strikes the sail, is of $54^\circ 44'$. The best position of the rudder, where it may have the greatest effect in turning

round the ship, is determined in like manner, and the same angle enters likewise into the determination of the figure of the rhombuses that form the bases of the cells in which the bees deposit their honey in the most frugal manner. (*See Honey-Comb*) But it is to be carefully observed, that when the sine of the angle ACE is to the radius as $\sqrt{2}$ to $\sqrt{3}$; or, which is the same thing, when its tangent is to the radius as the diagonal of a square to its side; this is the most advantageous angle only at the beginning of the motion of the engine; so that the sails of a common windmill ought to be so situated, that the wind may indeed strike them in a greater angle than that of $54^\circ 44'$. For it is demonstrable, that when any part of the engine has acquired the velocity c , the effort of the wind upon that part will be greatest, when the tangent of the angle in which the wind strikes it, is to the radius, not as the

$\sqrt{2}$ to 1 , but $\sqrt{2} \times \frac{9c}{4a} \times \frac{3c}{2a}$ to 1 , the velocity of the wind being represented by a . If, for example, $c = \frac{1}{2}a$; then the tangent of the angle ACE ought to be double of the radius; that is, the angle ACE ought to be of $63^\circ 26'$. If $c = a$; then ACE ought to be of $74^\circ 19'$. This observation is of the more importance, because, in this engine, the velocity of the parts of the sail remote from the axis bears a considerable proportion to the velocity of the wind, and perhaps sometimes is equal to it; and because a learned author, Daniel Bernoulli, has drawn an opposite conclusion from his computations in his hydrodynamics, by mistaking a minimum for a maximum; where he infers, that the angle in which the wind strikes the sail, ought to decrease as the distance from the axis of motion increases: that if $c = a$, the wind ought to strike in an angle of 45° ; and that if the sail be in one plane, it ought to be inclined to the wind, at a medium, in an angle of 50° . How he fell into these mistakes, is shewn by Maclaurin, in his Fluxions, § 914.

In like manner, though the angle ACE of $54^\circ 44'$ be the most advantageous at the beginning of the motion, when a ship sails with a side wind; yet it ought to be enlarged afterwards as the motion increases. In general, let Aa (*fig. 3.*) parallel to CB , be to AC , as the velocity which the engine has already acquired, to the direction CB , to that of the stream; upon AC produced, take AD to AC as 4 to 3 , draw DG parallel to CB , and let a circle described from the centre C with the radius Ca , meet DG in g ; and the plane CE shall be in the most advantageous situation for promoting the motion of the engine, when it bisects the angle aCg .

It is generally supposed, that a direct wind always promotes the motion of a ship, the sail being perpendicular to the wind, more than any side-wind; and this has been affirmed in several late ingenious treatises; but, to prevent mistakes, we are obliged to observe, that Maclaurin has demonstrated the contrary in his Treatise of Fluxions, § 913; where other mistakes of this second general problem in mechanics are given, to which we refer. See Maclaurin's Account of Sir Isaac Newton's Philosophical Discoveries, book II. chap. 3. p. 173.

Let ε denote the absolute effort of any moving force, when it has no velocity, and suppose it not capable of any effort when the velocity is W ; let F be the effort answering to the velocity V , then if the force be uniform, we shall have

$$F = \varepsilon \left(1 - \frac{V}{W} \right)$$

For it is the difference between the velocities W and V which is efficient, and the action, being constant, will vary as the square of the efficient velocity. Hence we shall have this analogy,

$$\phi : F :: (W - \phi)^2 : (W - V)^2,$$

and, consequently,

$$F = \phi \left(\frac{W - V}{W} \right)^2 = \phi \left(1 - \frac{V}{W} \right)^2 \quad \text{Q E D.}$$

Although the pressure of an animal is not actually uniform during the whole time of its action, yet it is nearly so, and therefore in general we may adopt this hypothesis, in order to approximate to the true nature of animal action. On which supposition the preceding proposition, as well as the following one, will apply to animal exertion. By retaining the same notation, we have also

$$W = \frac{V \sqrt{\phi}}{\sqrt{\phi} - \sqrt{F}},$$

which formula, applied to the motion of animals, gives the following theorem.

The utmost velocity with which an animal unimpeded, can move, is to the velocity with which it moves when impeded with a given resistance: as the square root of its absolute force to the difference of the square roots of its absolute and efficient forces.

Again, to investigate expressions by means of which the maximum effect, in machines whose motion is uniform, may be determined.

1. It follows from the observations made in the preceding part of this article, that when a machine, whether simple or compound, is put into motion, the velocities of the impelled and working points are inversely as the forces which are in equilibrio when applied to those points in the direction of their motion. Consequently, if f denotes the resistance when reduced to the working point, and v its velocity; while F denotes the force acting at the impelled point, and V its velocity, we shall have $F V = f v$, or introducing t , the time, $F V t = f v t$. Hence

In all working machines which have acquired an uniform motion, the performance of the machine is equal to the momentum of the impulse.

2. Let F be the effort of a force upon the impelled point of a machine, when it moves with a velocity V , the velocity being W , when $F = 0$, and let the relative velocity $W - V = u$.

Then, since $F = \phi \left(\frac{W - V}{W} \right)^2$, by the foregoing proposition, the momentum of impulse $F V$ becomes

$$F V = V \phi \left(\frac{u}{W} \right)^2 = \phi \frac{u}{W} (W - u);$$

because, since $W - V = u$, we have $V = W - u$.

Now making this expression for $F V$ a maximum, or supposing the constant quantities, and making

$$u (W - u) = \text{a maximum,}$$

we have, by throwing it into fluxions,

$$2 u \dot{u} W - 3 u^2 \dot{u} = 0, \text{ or } 2 W = 3 u, \text{ or } u = \frac{2}{3} W;$$

whence, again, $V = W - u = W - \frac{2}{3} W = \frac{1}{3} W$.

Consequently, when the ratio of V to v is given by the construction of the machine; and the resistance is susceptible of variation, we ought to load the machine more or less, till the velocity of the impelled point is one-third of the greatest

velocity of the force, in order that the work done may be a maximum.

Or the work done by an animal is the greatest when the velocity with which it moves, is one-third of the greatest velocity with which it is capable of moving when not impeded.

Again, since we have

$$F = \phi \frac{u^2}{W^2} = \phi \frac{\frac{2}{3} W^2}{W^2} = \frac{4}{9} \phi,$$

in the case of the maximum, we have also

$$F V = \frac{4}{9} \phi V = \frac{4}{9} \phi \cdot \frac{1}{3} W = \frac{4}{27} \phi W,$$

for the momentum of impulse, or for the work done when the machine is in the best state.

Consequently, when the resistance is a given quantity, we must make

$$V : v :: 9 f : 4 \phi,$$

which structure of the machine will give the maximum effect = $\frac{4}{27} \phi W$.

If we enquire the greatest effect on the supposition that ϕ only is variable, we must make it infinite in the above expression for the work done, which would then become

$$W F, \text{ or } W \frac{V}{\phi} f, \text{ or } W \frac{V}{\phi} f t,$$

including the time in the formula.

Whence we come to this important conclusion, viz.

That the sum of the agents employed to move a machine may be infinite, while the effect is finite.

For the variations of ϕ , which are proportional to this sum, do not influence the above expression for the effect. The last theorem may be applied to the action of men and of horses, with more accuracy than might at first be supposed. Observations have been made on men and horses drawing a lighter along a canal, and working several days together. The force exerted was measured by the curvature and weight of the track rope, and afterwards by a spring steel-yard. The product of the force thus ascertained into the velocity per hour, was considered as the momentum; and in this way the action of the men was found to be very nearly as $(W - V)^2$. The action of the horses, loaded so as not to be able to trot, was nearly as $(W - V)^2$, or as $(W - V)^2$. Hence the hypothesis above adopted may, in many cases, be safely assumed. According to the best observations, the force of a man at rest is on an average about seventy pounds, and the utmost velocity with which he can walk is about six feet per second, taken at a medium. Hence in the above theorems $\phi = 70$, and $W = 6$; consequently $F = \frac{4}{9} \phi = 31 \frac{1}{3}$ lbs, the greatest force a man can exert when in motion, and he will then move at the rate of $\frac{1}{3} W$, or two feet per second, or rather less than 1 mile per hour.

The strength of a horse is generally reckoned about six times that of a man, that is, about 420 lbs. at a dead pull. His utmost walking velocity is about ten feet per second; and therefore his maximum action will be $6 \times 420 = 2520$ lbs, and he will then move at the rate of $\frac{1}{3}$ of 10, or $3 \frac{1}{3}$ feet per second, or nearly 2 miles per hour. In both these instances we suppose the force to be exerted in drawing a weight, by a cord running over a pulley, which makes its direction horizontal.

The theorem above given may serve to shew under what points of view machines ought to be considered by those who would labour beneficially for their improvement. The first object of utility is in furnishing the means of giving to

to the moving force the most commodious direction, and when it can be done of causing its action to be applied immediately to the body to be moved. These, it is true, can rarely be united, but the former may, in most instances, be accomplished; of which the use of the simple lever, pulley and wheel and axle, furnish many examples. The second object gained by the use of machines, is an accommodation of the velocity of the work to be performed, to the velocity with which alone a natural power can act. Thus, whenever the working power acts with a certain velocity, which cannot be changed, and the work must be performed with a greater velocity, a machine is interposed round a fixed support, and the distance of the impelled and working points are taken in the proportion of the two given velocities. But the essential advantage of machines, and that in fact which properly appertains to the theory of mechanics, consists in augmenting, or rather modifying the energy of the moving power, in such a manner that it may produce effects, of which it would otherwise have been incapable. Thus a man might carry up a flight of steps twenty pieces of stone, each weighing say 30lbs. one by one, in as small a time as he could, with the same labour, raise them all together with a piece of machinery, that would have the velocities of the impelled and working points as twenty to one, and in this case the instrument would furnish no real advantage except in saving his steps. But if a large block of 20 times 30, or 600lbs. were to be raised to the same height, it would far exceed his utmost efforts to accomplish it, without the intervention of some machine. Or the same purpose may be illustrated somewhat differently, confining the attention still to those machines whose motion is uniform. The product $f \times v$ represents, during the unit of time, the effect which results from the motion of the resistance; this motion being produced in any manner whatever. If it be produced by applying the moving force immediately to the resistance, it is necessary, not only that the product $FV = f \times v$, but also at the same time $F = f$ and $V = v$; if, therefore, as most frequently happens, f be greater than F , it will be absolutely impossible to put the resistance in motion, by applying the moving power immediately to it. Now, machines furnish the means of disposing of the product FV in such a manner, that it may always be equal to $f \times v$, however much the factors FV may differ from the analogous factors in $f \times v$; and consequently of putting the system in motion, whatever may be the excess of f above F . Or, generally, as Prony remarks, (*Arén. Hydraul. art. 501.*) machines enable us to dispose of the factors FV in such a manner, that while that product continues the same, its factors may have to each other any ratio at pleasure. Thus, to give another example: suppose that a man, exerting his strength immediately upon a mass of 25lbs. can raise it vertically, with the velocity of four feet per second; the same man acting upon a mass of 1000lbs. cannot give it any vertical motion, though he exerts his utmost strength, unless he has recourse to some machine. Now he is capable of producing an effect equal to $25 \times 4 \times t$; the letter t being introduced, because, if the labour be continued, the value of t will not be infinite, but comprised within assignable limits. Thus we have $25 \times 4 \times t = 1000 \times v \times t$; and, consequently, $v = \frac{1}{4}$ th of a foot. This man may, therefore, with a machine as a lever, or axis in *perpetua*, cause a mass of 1000lbs. to rise $\frac{1}{4}$ th of a foot in the same time that he could raise 25lbs. 4 feet without a machine; or he may raise the greater weight as far as he lists, by employing forty times as much time. From what has now been said on the extent of the effects which may be attained by machines, it will be seen, that so long as a moving force exercises a determinate

effort with a velocity likewise determinate, or so long as the product of these is constant, the efforts of the machine will remain the same: so that under this point of view, supposing the preponderance of the effort of the moving power, and abstracting from inertia and friction or material resistance, the convenience of application, &c., all machines are equally perfect. But from what has been shewn in the preceding part of this article, a moving force may, by diminishing its velocity, augment its effort, and reciprocally. There is, therefore, a certain effect of the moving force, such that its product by the velocity, which comports to that effort, is the greatest possible. Now admitting of the truth of the results in the preceding propositions $V = \frac{1}{2}W$, or $F = \frac{1}{2}R$, and these two values obtaining together their product, $\frac{1}{2} \times W$ expresses the value of the greatest effect with respect to the unit of time; and in practice it will always be advisable to approach as nearly to these values as circumstances will admit, for it cannot be expected that it can always be exactly attained. But a small variation will not be of much consequence: for by a well known property of those quantities, which admit of a proper maximum or minimum, a value assumed at a moderate distance from either of these extremes, will produce no sensible change in the effect.

If the relation of F to V followed any other law than that which we have assumed, we should find from the application of that law, values of F and V , less different from the preceding, but the general method would be still exactly the same.

With respect to practice, the grand object in all cases should be to procure an uniform motion. Because it is from that which, *ceteris paribus*, the greatest effect, always results. Every irregularity in the motion wastes some of the impelling power, and it is the greatest only of the varying velocities which is equal to that, which it would acquire if it moved uniformly throughout: for while the motion accelerates, the impelling power is greater than what it takes the resistance at that time opposed to it, and the velocity is less than what the machine would acquire, if moving uniformly; and when the machine attains its greatest velocity, it attains it because the power is not then strong enough to move the resistance. In both these cases, therefore, the performance of the machine is less than if the power and the resistance were exactly balanced, in which case it would move uniformly. Indeed, thus, when the motion of a machine, and particularly a very powerful one, is irregular, there are, as we have already remarked in the preceding part of the article, continual repetitions of strains and lulls, which soon derange, and ultimately destroy the whole structure.

In the preceding remarks and propositions relative to the maximum effect of machines, we have considered ourselves under an interesting chapter on this subject. General Principles of Mechanics, in which the theory is pursued to a much greater length than our limits will admit of, both with regard to machines and motions are uniform and accelerated, and to which we would refer the reader for further information. See also Prony's "Architecture Hydraulique" tom. iii. 487 to 507; and the last edition of Ferguson's Mechanics by Belcher, in which an interesting paper on this subject is given by professor Leslie.

MACHINE for taking down extemporaneous pieces of music, commonly called *volantines*. Such a contrivance has been long among musical *diffusions* of the most important kind. To fix such fleeting sounds as are generated in the extatic moments of enthusiasm, while the bright-eyed

"Scatters from her pictured urn,
Thoughts that breathe, and notes that burn,"

would be giving permanence to ideas which reflection can never find, nor memory retain.

The first idea of such a contrivance being practicable was suggested to the Royal Society of London, in a paper written by the late Rev. Mr. Creed, and sent to the president, 1747, under the following title:

"A demonstration of the possibility of making a machine that shall write *extempore voluntaries*, or other pieces of music, as fast as any master shall be able to play them, upon an organ, harpsichord, &c. and that in a character more natural and intelligible, and more expressive of all the varieties those instruments are capable of exhibiting, than the character now in use."

This paper was published the same year in the Philosophical Transactions, N. 183, and, afterwards, in Martyn's Abridgment, vol. x. p. 266; and the author's idea always appeared to us so feasible, that we have long wondered at its not having been executed by some ingenious English mechanic.

The first mention that we can find to have been made at Berlin, of such a contrivance, was in 1752, in a printed "Weekly Account of the most remarkable Discoveries in Nature and Science." In 1753, an ample description of such a machine appeared in the same weekly publication: and here, in an elaborate preface, the author points out the great want of such a piece of mechanism, its utility, and properties; and concludes with saying, that this machine, so big with advantages to music and musicians, is the *particular invention*, Besondere Erfindung, of M. Unger.

The description preceded the execution some time. The invention was here only recommended to the public, and offered to be completed, and applied to a keyed instrument, at a small expence. It was M. Hohlfeld who afterwards constructed the machine, and rendered it so perfect, that we were assured by a great performer, who tried it upon a clavichord, that there was no refinement in music which it could not express, except *tempo rubato*.

The description of the Berlin machine so much resembles that proposed by Mr. Creed, that we shall not insert it here, but refer our readers to the Philosophical Transactions, where he will find that the machine was to consist of two cylinders, which were to be moved by clockwork, at the rate of an inch in a second of time; one of these was to furnish paper, and the other was to receive it when marked by pins or pencils, fixed at the ends of the several keys of the instrument to which the machine was applied. The paper was to be previously prepared with red lines, which were to fall under their respective pencils.

The chief difficulties in the execution, which have occurred to English mechanics, with whom we have conversed on the subject, were, the preparation of the paper for receiving the marks made by the keys; and the kind of instrument which was to serve as a pencil, and which, if hard and pointed, would, in the *forte* parts, tear the paper; and if soft, would not only be liable to break when used with violence, but would be worn unequally, and want frequent cutting.

In the Berlin machine the pencils were approximated according to Mr. Creed's idea, and made to terminate in a very narrow compass, so that paper of an uncommon size was not requisite; but it was not found necessary to prepare the paper, as proposed in the Philosophical Transactions: for the degree of gravity or acuteness of each sound was ascer-

tained by a ruler applied to the marked paper, when taken off the cylinder.

About the year 1780, the late ingenious and marvellous mechanic Merlin, stimulated by the reports of this machine having been successfully constructed in Germany, and by our earnest recommendation of the undertaking, went to work, and apparently vanquished all the difficulties of construction, except the time inevitably necessary for its completion; as he was never able to simplify the mechanism so much as to render its appropriation within the reach of great composers and voluntary players in general, to whose use only it seems to belong; he disposed of his model to a foreign nobleman, who had it conveyed to Germany, and we believe never fabricated another machine of the same kind. See MERLIN.

MACHINE, in *Dramatic Poetry*, is when the poet brings some divinity or supernatural being upon the stage: to perform some exploit, or solve some difficulty, out of the reach of human power.

The machines of the drama are gods, angels, ghosts, &c. They are so called from the machines or contrivances by which they are represented upon the stage, and afterwards removed again.

Hence the use of the word machine has also passed into the epic poem; though the reason of its name be there wanting. It denotes, in both cases, the intervention or ministry of some divinity; but as the occasion of machines in the one and the other is somewhat different, the rules and laws of managing them are different likewise.

The ancient dramatic poets never brought any machine on the stage, but where there was an absolute necessity for the presence of a god; and they were generally laughed at for suffering themselves to be reduced to such a necessity. Accordingly, Aristotle lays it down as an express law, that the unravelling of the piece should arise from the fable itself, and not from any foreign machine, as in the *Medea*. Horace is somewhat less severe, and contents himself with saying, that the gods should never appear, unless where the *nodus*, or knot, is worthy of their presence; "*Nec deus interit, nisi dignus vindice nodus—inciderit.*" But it is quite otherwise with the epopee; in that there must be machines every where, and in every part. Homer and Virgil do nothing without them. Petronius, with his usual fire, maintains, that the poet should deal more with the gods than with men; that he should every where leave marks of his prophetic raptures, and of the divine fury that possesses him; that his thoughts should be all full of fables, that is, of allegories and figures: in fine, he will have a poem distinguished from a history in all its parts; not so much by the verses, as by that poetical fury, which expresses itself wholly by allegories; and does nothing but by machines, or the ministry of the gods. A poet, therefore, must leave it to the historian to say, that a fleet was dispersed by a storm, and driven to foreign shores; and must himself say, with Virgil, that Juno went to seek *Æolus*; and that this god, at her request, turned the winds loose against the Trojans: he must leave the historian to write, that a young prince behaved with a great deal of prudence and discretion on all occasions; and must say, with Homer, that Minerva led him by the hand in all his enterprises: let an historian say, that Agamemnon, quarrelling with Achilles, hath a mind to shew him, though mistakenly, that he can take Troy without his assistance; the poet must say, that Thetis, piqued at the affront her son had received, flies up to heaven, thence to demand vengeance of Jupiter: and that this god, to satisfy her, sends the god *Somnus*, or Sleep, to Agamemnon,

MACHINE.

to deceive him, and make him believe that he shall take Troy that day.

It is thus that the epic poets used machines in all parts of their works; in the *Iliad*, *Odyssey*, and *Æneid*, the proposition mentions them; the invocation is addressed to them; and the narration is full of them: they are the causes of actions; they make the knots, and at last they unravel them. This last circumstance is what Aristotle forbids in the drama; but it is what Homer and Virgil have both practised in the epopea. Thus Minerva fights for Ulysses against Penelope's lovers; helps him to destroy them; and, the next day, herself makes the peace between Ulysses and the Ithacans; which closes the *Odyssey*. The use of machines in the epic poem is, on some accounts, entirely opposite to what Horace prescribes for the theatre. In tragedy, that critic will never have them used without an absolute necessity; whereas, in the epopea, they should never be used, but where they may be as well let alone; and where the action appears as if it did not necessarily require them. How many gods and machines does Virgil implore to raise the storm that drives Æneas into Carthage; which yet might easily have happened in the ordinary course of nature.

In Milton's *Paradise Lost*, most of the actors are supernatural personages; and in Voltaire's *Henriade*, the poet has made excellent use of St. Louis.

Machines, in the epic poem, therefore, are not contrivances of the poet, to recover himself after he has made a false step, nor to solve any difficulty peculiar to some part of the poem; but it is the presence of a divinity, and some supernatural and extraordinary action, which the poet inserts in most of the incidents of his work, to render it more majestic and admirable, and to train up his readers to piety and virtue. This mixture should always be so managed, as that the machines may be retrenched, without retrenching any thing from the action. As to the manner in which the machines are to act; it may be observed, that in the old mythology, there are gods both good, bad, and indifferent; and that our passions may be converted into so many allegorical divinities: so that every thing, both good and bad in a poem, may be attributed to these machines, and may be transacted by them. They do not, however, always act in the same manner; sometimes they act without appearing, and by simple inspirations, which have nothing in them extraordinary or miraculous; as when we say, the devil suggested such a thought, &c. The second manner of acting is entirely miraculous; as when a divinity presents itself visible before men, so as to be known by them; or when they disguise themselves under some human form without discovering themselves. The third manner partakes of each of the two, and consists in oracles, dreams, and extraordinary inspirations: all which Boileau calls *divi machines*.

All these manners ought to be so managed as to carry a verisimilitude: and though verisimilitude be of a vast extent in machines, as being founded on the divine power, yet it has its bounds. See farther, on the importance and use of machinery, the article *Epic Poem*.

MACHINE, in *Agriculture*, a term applied to instruments of various kinds which are contrived either for the purpose of lessening labour or performing the different operations and processes of the art with greater accuracy and correctness, such as those of sowing, drilling, reaping, threshing, winnowing, and a great many others. The term is most commonly employed when the nature of the tool is of the more complex kind. It may, however, be employed with propriety in many other circumstances. See *THRESHING Machine*.

VOL. XXI.

MACHINE, *Architectonical*, is an assemblage of pieces of wood so disposed, as that, by means of ropes and pulleys, a small number of men may raise vast loads, and lay them in their places. Such are cranes, &c.

It is hard to conceive what sort of machines the ancients must have used to raise those immense stones found in some of the antique buildings. See MACHINE, *supra*.

MACHINE, *Blowing*. See BELLOWS, and BLOWING MACHINE.

MACHINE, *Bruising*, a contrivance for the purpose of crushing and reducing gram, pulse, malt, and other articles, some of which are employed as team food. Machines of this kind are made in London by Rowntree and others.

MACHINE, *Chaff-cutting*, a tool contrived for the purpose of cutting straw, hay, and other similar materials into chaff for the purpose of food for team-horses, and other animals. There are various descriptions of this kind of machinery which act on very different principles, and some of them have lately undergone very much improvement. See CHAFF-CUTTER.

MACHINE, *Draught*, a simple contrivance formed for the purpose of ascertaining the force or power of draught, in drawing ploughs, and various other implements where draught is required. A machine of this sort, invented by Mr. More, late secretary to the Society for the Encouragement of Arts, &c. in London, is thus described by Mr. Young in the first volume of the *Annals of Agriculture*. It is a spring coiled within a cylindrical case, having a dial-plate, marked with numbers like that of a clock, and so contrived that a hand moves with the motion of the spring, and points to the numbers in proportion as the force is exerted: for instance, when the draught equals 1 cwt. over a pulley, the hand points to *fig. 1*; when the draught is equal to 2 cwt. it points to *fig. 2*; and so on. Till this very useful machine was invented, Mr. Young says, it was exceedingly difficult to compare the draught of different ploughs, as there was no rule to judge but by the exertions of the horses as apparent to the eye; a very indecisive mode of ascertaining their force.

MACHINE, *Drill*, that sort of tool which is employed in sowing and depositing various kinds of grain, pulse, and small seeds, in drills or rows. They are very differently formed, according to the purposes for which they are intended, and the manner of drilling which is intended to be practised.

They require to be constructed with great correctness, and in as simple a manner as possible, in order that they may perform their work with accuracy, both in respect to the drills, the quantity of seed, and the depth of depositing it in the soil.

In the choice of this sort of machinery, the farmer should be principally directed by the nature and extent of his land, the situation which it possesses, and the kinds of crops which he intends to cultivate. They have lately been so contrived, as, by slight alterations in the sowing parts, to be capable of not only sowing grain as well as small seeds, but of executing the work at different distances, and in a greater or less number of rows at once, as circumstances may require.

There are several machines of this nature, which perform the business in a very exact and regular manner; among which are Cook's, Bailey's, Amos's, McDougal's, and many others; each of which sow several rows at the same time, and some of them are likewise capable of forming horse-hoes.

Besides these, there are also drills constructed for particular

M A C H I N E.

cular sorts of crops, as those of peas, beans, turnips, &c. See *Plough Drill*, and *Turnip Drill*.

A drill machine, invented by Mr. Robert Salmon of Woburn, Bedfordshire, which obtained the premium given by the duke of Bedford, at Woburn sheep-shearing, a few years ago, for the best newly-invented agricultural implement, is described below. This machine drills and sows at the same time; and the principal improvement in it, as in Cook's drill, and others, consists in constructing it in such a manner, that the workman who holds the drill has a perfect command upon it, with respect to the direction in which it shall move, even though the horse which draws it should deviate from the line the drill is intended to follow. In *Plate (Machines) Agriculture*, is given a descriptive representation of the machine, in which *fig. 1* is a section of a part, *fig. 2* an elevation of the same, *fig. 4* is a perspective view of the whole, and *figs. 3* and *5* detached parts.

The great wheels, A, A, *fig. 4*, have their axle-trees attached to the bed B, to which are framed the long handles, D, D, forming a frame independent of the remainder of the machine, and having no connection with it, except in the middle of the bed B, where a short beam, E, is jointed to it, as is well explained in *fig. 1*; the other end of this beam is mortised into a cross beam F, to which the three drills, G, G, G, are fixed; a frame formed of two horizontal pieces, H, H, *figs. 2* and *4*, and four vertical pieces, I, I, I, I, is erected upon F; the handles, D, D, pass between H, H, but are not fixed thereto; the hook a, by which the machine is drawn, is fixed to the two middle uprights, I, I, and a strong chain leads to the harness of the horse employed; K is the feed-box supported from H, H, by two uprights for the purpose; the box is a frustum of a pyramid, and joins at the bottom to a prismatic box, containing the feed-roller b, *fig. 1*, which is exactly the same length as the box, and comes through its ends, its pivots being supported by a piece of iron-plate fixed at the end of the box, as seen in *fig. 4*; a brush, d, presses upon the roller, and is adjustable by a screw that it may always bear upon it with an equal degree of force; a number of notches is cut in the circumference of the roller, and as the box K is full of seed, it always rests upon the roller; when it turns round, it takes one of the notches full of seed, and passing it by that means under the end of the brush d, delivers it into a tin-plate tube r, which conveys it down into the furrow made by the drill; the roller has three series of notches answering to the three drills G, G, G; at e, a piece of leather presses against the roller, to prevent any seed getting down, except that which passes under the brush d; f is a slider, which stops the seed from coming down to the roller, when shoved in, and is used when the machine is required to advance without sowing, or when a lesser number of rows is required to be sown. The roller is turned by means of an endless chain, q q, passing round a groove made in the middle of the roller, from thence it proceeds through a block of pulleys at t, shewn separate in *fig. 5*, to a small wheel b; the block, t, is made of cast-iron, and slides freely up and down between the two innermost uprights, I, I, of the frame; its weight keeps the chain always tight, and prevents it from slipping without turning the roller; the wheel, b, is fixed upon an axle p, on the end of which is a cog-wheel, turned by another cog-wheel on the nave of the great wheel A; these wheels are enclosed in a box l, which likewise contains a contrivance for disengaging the wheels, shewn on a larger scale in *fig. 3*, where p is a section of the axle p, passing through a long staple fixed to the bed B; it can slide up and down in this staple, except when confined by a catch o, pressed against it by a spring. In the present

position, the cog-wheels are engaged to work together: but by pulling the cords m and l, the former draws back the catch o; and the other, by means of the crooked lever n n, raises up the axle p, and disengages the cog-wheels; the return of the catch, o, prevents its descent; the cords, l and m, are conducted to the end of the handles, D, D where they are both attached to one handle, in reach of the workman who guides the machine.

The operation of the drill is exceedingly simple. As the horse draws it along by means of the chain, the drills, G, G, G, make the furrows, and the feed-roller delivers the seed in small quantities, and at regular intervals into them. As the hook a, from which the chain draws, is placed nearly in the centre of the machine, it will easily be made to follow any other line than that in which the horse draws, by turning the handles, D, D, to one or other side. This alters the direction of the wheels, A, A, which immediately proceed in that line, and the drill follows them. This quality is of the greatest consequence in making straight work. L is a cross piece fixed to the handles, D, D, and supporting a handle M, by which, and one of D, the workman holds when he guides the drill, as he is then in a position to see the drills made last, and adapt the present ones to them; the wheel always going in the last made drill. Another handle, similar to M, is fixed to the other end of L, to be used when the machine is on the other side of the work done last. The drills are fixed to the piece F by screws, and their distance from one another can be altered at pleasure. The feed-box containing the roller is made in two halves, connected by hooks, so that it can be taken apart, and the roller removed for a fresh one to be put in with different sized notches, for sowing a different kind of grain.

The drawing was taken from a machine made by Mr. Shepherd, Woburn, and exhibited at Woburn sheep-shearing, June 1808. Mr. Salmon has made a great number of the same pattern, which are now in use, and are found to answer well. Several of them have five drills instead of three, and are in that case worked by one horse.

In this drill, at whatever distance the shares are placed to go from each other, the distance from the wheels to the two outside rows is always equal thereto; consequently, when at work, one or the other of the wheels always runs in the last made drill, thereby gauging accurately the interval between each bout the drill goes; and as the holder always goes in the line of the wheel, he can distinctly see and correct the smallest error that may have been made in any previous bout.

In all cases, one horse is sufficient to draw this drill either for three or more rows, as little depends on the horse's inclination; and a driver can be dispensed with, where tractable horses are used. As in all machines of this sort, in proportion to the number and distance of rows made, so will be the quantity of work performed.

MACHINE, *Electrical*. See *ELECTRICAL Machine*.

MACHINE, *Fan*, in *Agriculture*, a common name applied to that sort of tool which is employed in removing the chaff from the grain. See *WINNOWER Machine*.

MACHINE, *Land-Levelling*, the name of an useful machine, invented by Mr. David Charles, for the purpose of rendering high ridges and other inequalities, in such lands as are in a state more level and even in their surfaces. It would seem probable that no effective implement of this sort has hitherto been introduced. But such a machine is said, in "Transactions of the Society of Arts," to be useful and necessary even in the most fertile parts of the country, where the improved system of drill-husbandry has been

MACHINE.

been introduced, or even where there is any attention to the waste of time, or to the ease of cattle in the act of ploughing; in order to get rid of crooked or unequal ridges, without either a summer fallow by cross ploughing, or else by frequent repetitions of ploughing in the winter and spring, which the humidity of this climate will not allow in every kind of soil. "Fourteen acres of land were reduced with this tool by the inventor to a perfect level, where the crowns of the ridges were about two feet higher than the furrows, and where they were crooked and of unequal breadths. But the chief success has been upon a field of eight acres, which lay in an unprofitable state, and which is a deep clay, that had produced a crop of wheat from an old lay sod the former year, without any manure, which was winter ploughed, and lay in that state until the machine was introduced the first dry weather in April. It was preceded by two horse ploughs, taking perhaps a square of an acre at once: these loosened the soil the depth of a common furrow, and twice the breadth across the ridges. The levelling machine followed, drawn by two oxen and two horses, with a man at each handle, to press it down where the height was to be removed, and to lift up the body by the handles where it was to be discharged. Thus, four men, one driver, and eight head of cattle, will more effectually level from half an acre to three roods in one day, according as the earth is light or heavy, than sixty or eighty men would accomplish with harrows and shovels, &c. even with the assistance of a plough. In sandy ground, where the depth of one furrow will bring a l to a level, as much, of course, will be done in one day as two ploughs can cover;" but in this case, the ground required to be gone over several times. It is further stated, that "after this field was levelled, the backs of the ridges, as they are termed, which were stripped of their vegetable mould, were ploughed up, the furrows not requiring it. They were also harrowed, and the field copiously manured with lime-compost, harrowed in, and broke into nine feet ridges, perfectly straight, in order to introduce Duckitt's drill. It was sown under furrow, broad-cast, the last of it not until the 13th of May, and was cut down a reasonable crop the 4th of September." And "the field now lies in proper form, well manured, with the advantage of a fair crop from heavy tenacious ground, without losing a season, and in a year by no means favourable." The writer is "well aware there are many shallow soils, where it may be hazardous to remove the enriched surface, and trust perhaps one half of the land for a crop that had never before been exposed to the atmosphere; but where the soil is sufficiently deep, or there is a good under-stratum, with manure at hand to correct what is sour for want of exposure and tillage, it is evident, from this experiment, that no risk is run." And in order "to avoid the expence of a fallow, and to lay out ground in straight and even ridges, even where drill husbandry is not practised, should be objects to every rational farmer: but where the new system is intended to be adopted, it becomes indispensibly necessary. In laying down lawns, parks, &c. where furrows are an eye-sore, or places inaccessible to wheel-carriages from their declivity, and from which earth is to be removed, it will also be found equally useful." Besides these, there are many other cases in which the old rounded ridges may be levelled down with great advantage, either by this or some other means.

A representation of this machine is given at *fig. 1.* in *Plate (Machines) Agriculture*, in which *a*, *fig. 2.* is a part of the pole, to which the oxen or horses which draw the machine are fastened, and which is attached to the machine by a pin at *b*; *c, c,* the two wheels, shod with iron, which run upon the axle *d*; *e, e,*

the upper frame work of the machine, extending from the axle to the extremity of the handles, *f, f.* and secured firmly by the cross pieces, *g, g,* the curved iron sliders of the machine, which may be raised or depressed a little by means of the pins, *h, h,* which pass through holes in the wood-work, and also in the iron sliders. These sliders form one piece with the back iron scraper *i*, in the manner more fully explained in *fig. 3, k*, the wooden back of the machine, which should be made strong, to resist the weight of the earth when collected therein. The iron scraper should be firmly secured to this by screws and iron work; *l, l,* the wooden sides of the machine, firmly connected with the back and frame work, in order to assist in collecting the earth to be removed; *m*, a strong cross piece, into which the ribs which support the back are well mortised.

The interior part of the back of the machine is shewn at *k*, in *fig. 3*: *i*, the iron scraper, sharp at the bottom, firmly screwed to the back of the machine; *g, g,* parts of the side irons or sliders, shewing the mode in which they are united with the scraper *i*; *m*, the cross piece already described.

MACHINES, Military, among the *Ancients*, were of three kinds: the first serving to launch arrows, as the scorpion; or javelins, as the catapulta; or stones, as the balista; or fiery darts, as the pyrobolus: the second serving to beat down walls, as the battering ram and terebra; and the third to shelter those who approach the enemies wall, as the tortoise or testudo, the vinea, pluteus, and the towers of wood. These machines, together with their proportions and properties, are described in the works of Vitruvius, Ammianus Marcellinus, and other writers. Mr. Grose has given descriptions and drawings of these in the *first* volume of his "Military Antiquities," chap. xii.

MACHINE, Stone-lifting, in *Agriculture*, an implement of the triangle kind, similar to that used by wood-cutters for weighing bark, constructed for the purpose of raising large stones of some tons weight used in the northern parts of Scotland, and many other places. It is supposed to save much expence in powder and boring as well as labour, three men being sufficient to work it. It is described in the *Agricultural Survey of Perthshire* in this manner.

"The three legs, *a d*, *b d*, and *c d*, which are shewn at *fig. 4*, are beams of any hard wood, four inches thick; six inches broad, and about fourteen feet long. Their thinnest side points inwards, which gives them more strength. Their feet form on the ground an equilateral triangle *abc*, and their three tops at *d* are fixed together by an iron rod, which passes through each. The two legs *a d* and *b d* are fixed to one another by the windlafs *k*, and by the cross-bar *o p q*. There are two pulleys *e* and *f*, with an iron hook two inches in circumference to each; *g g g* may be (more than one, but rather) one iron chain which goes round the stone *n*, while lying in the ground at *m*. below its greatest diameter, or where it begins to become narrow. This chain consists of rounded links, which are about three inches long, and about the thickness of a man's little finger. It has a hook at one end, that may be put into any hook towards the other end, which will make it embrace the stone exactly, and be of the same circumference, where the stone touches the earth; *h g*, *h g*, *h g*, are shorter chains of the same workmanship, whose hooks are fixed into links of the surrounding chain at *g g g*, and to on round the stone, having the corresponding link of each fixed on the hook of the lower pulley at *h*. The whole rope must be of the same thickness with the two great hooks, two inches in circumference.

"All things being thus prepared, two men turn round the handles of the cylinder, and the waggoner adding them

by applying a lever to any side of the stone that seems to be firmest, they force it aloft, and hold it up at the proper height, until the diver put his carriage backward between *b* and *c*, which carriage ought to have a strong frame upon four low stout wheels; then the stone is let gently down and carried away."

By this sort of machine large stones or other bodies can be raised and removed without any great difficulty.

MACHINE, Threshing, a contrivance made use of instead of the flail for threshing corn and other feed crops. See *THRUSHING Machine*.

MACHINE, Water, or Hydraulic, is either used to signify a simple machine, serving to conduct or raise water; as a sluice, pump, &c. or several of these acting together, to produce some extraordinary effect; as the

MACHINE of Marli. See *MARLI*. See also *FIRE-engine*, *STEAM-engine*, and *WATER-wheels*.

MACHINE, Water-raising, a sort of machine contrived for the purpose of raising water a few feet high by the power of the wind, for the purpose of draining morasses, or of watering lands on a higher level, and other similar uses. A section of it is given at *fig. 5*, and it is described by the author of the *Philosophy of Agriculture and Gardening* to "consist of a windmill sail placed horizontally, like that of a smoke-jack, surrounded by an octagon tower; the diverging rays of this tower, *a b, a b*, may consist of two-inch deals only, if on a small scale, or of brick-work if on a larger one. These upright pillars are connected together by oblique horizontal boards at *A B*, by which boards placed horizontally from pillar to pillar in respect to their length, but at an angle of about 45 degrees in respect to their breadth, so as to form a complete octagon, including the horizontal windmill sail near the top of it; the wind, as it strikes against any of them, from whatever quarter it comes, is bent upwards, and then strikes against the horizontal wind-sail. These horizontal boards, which form the sides of the octagon, may either be fixed in their situations, or be made to turn upon an axis a little below their centres of gravity, so as to close themselves on that side of the octagon tower most distant from the wind. It may be supposed that the wind thus reflected, would lose considerably of its power before it strikes on the wind-sail; on fixing a model of such a machine, however, on the arm of a long whirling lever, with proper machinery to count the revolutions of the wind-sail, when thus included in a tower, and moving horizontally; and then when moved vertically, as it was whirled on the arm of the lever with the same velocity, it was found on many trials by Mr. Edgeworth, in Ireland, and Dr. Darwin, at Derby, that the wind, by being thus reverted upwards by a fixed planed board, did not seem to lose any of its power. And as the height of the tower may be made twice as great as the diameter of the sail, there is reason to conclude, the doctor thinks, that the power of the horizontal wind-sail may be considerably greater, than if the sail was placed nearly vertically opposed to the wind in the usual manner. At the bottom of the shaft of the wind-sail is placed a centrifugal pump with two arms at *D, C*, which consists simply of an upright bored trunk, or cylinder of lead, with two opposite arms with an adapted valve at the bottom to prevent the return of the water, and a valve at the extremity of each arm to prevent any ingress of air above the current of the water as it flows out; *c c c c* is a circular trough to receive the streams of water from *C* and *D*, to convey them where required in any particular operation or process.

And at *fig. 6* is another machine, invented by Mr. Sergeant, of Whitehaven, calculated for raising or forcing

water in particular cases, as for domestic or other uses. It is extremely simple and cheap in its construction, the whole, exclusive of the pump pipes, &c. not costing more than five pounds. The object for which it was particularly contrived was that of raising water for the supply of a gentleman's house from a stream running at the distance of about 140 yards. In which intention a dam was made a little distance above, so as to cause a fall of about four feet, the water being brought by a wooden trough, into which was inserted a piece of two-inch leaden pipe, a part of which is seen at *a*, in the figure; the stream of this pipe is so directed as to run into the bucket *b c*, when the bucket is elevated; but as soon as it begins to descend, the stream flows over it, and goes to supply the wooden trough, or well, in which the foot of the forcing pump, *c*, stands, of three inches bore; *d* is an iron cylinder attached to the pump rod, which passes through it, which is filled with lead, and is in weight about 240 pounds. This is the power which works the pump, forcing the water through 240 feet of inch pipe from the pump up to the house. At *e* a cord is fixed, which, when the bucket comes to within four or five inches of its lowest projection, becomes stretched, and opens a valve at the bottom of it, through which the water discharges itself. This sort of pump may be found very beneficial in a variety of instances where its application can be admitted.

MACHINE, Wind. See *ANEMOMETER*, and *WIND Machine*.

MACHINERY, in the Lyric theatre, or Opera-house. In the early operas of Italy, during the 17th century, it seldom happened that the names of the poets, composers, or singers, were recorded in printed copies of the words; though that of the machinist was seldom omitted; and much greater care seems to have been taken to amuse the eye than the ear or intellect of those who attended these spectacles.

In 1675, we are told, in the *Theatrical Annals of Venice*, that a musical drama, called *La Divisione del Mondo*, written by Giulio Cesare Corradi, and set by Legrenzi, excited universal admiration, by the stupendous machinery and decorations with which it was exhibited. And in 1680, the opera of *Berenice*, set by Domenico Freschi, was performed at Padua in a manner so splendid, that some of the decorations recorded in the printed copy of the piece seem worthy of notice in this article. The musical drama consisted of poetry, music, dancing, machinery, and decorations; and it would be curious to point out the encephalometers which any one of these constituent parts at different periods has made upon the rest. In the beginning it was certainly the intention of opera legislators to favour Poetry, and make her mistress of the feast; and it was a long while before Music absolutely took the lead. Dancing only slept into importance during the last century; but very early in the 17th century, machinery and decorations were so important, that little thought or expence was bestowed on poetry, music, or dancing, provided some means could be devised of exciting astonishment in the spectators, by splendid scenes and ingenious mechanical contrivances.

In the opera of *Berenice* just mentioned, there were choruses of one hundred virgins, one hundred foldiers, one hundred horsemen in iron armour, forty cornets of horse, six trumpeters on horseback, six drummers, six ensigns, six sacbuts, six great flutes, six minstrels playing on Turkish instruments, six others on octave flutes, six pages, three sergeants, six cymbalists, twelve huntmen, twelve groomes, six coachmen for the triumph, six others for the procession, two lions led by two Turks, two elephants by two others, *Berenice's* triumphal car drawn by four horses, six other cars with prisoners and spoils drawn by twelve horses, six coaches

coaches for the procession. Among the scenes and representations in the first act, was a vast plain, with two triumphal arches; another, with pavilions and tents; a square prepared for the entrance of the triumph; and a forest for the chase. Act II. the royal apartments of Berenice's temple of vengeance; a spacious court, with a view of the prison; and a covered way for the coaches to move in procession. Act III. the royal dressing room, completely furnished; stables with one hundred live horses; portico adorned with tapestry; a delicious palace in perspective. And besides all these attendants and decorations, at the end of the first act, there were representations of every species of chase: as of the wild boar, the stag, deer, and bears; and at the end of the third act, an enormous globe descends from the sky, which opening divides itself into other globes that are suspended in the air, upon one of which is the figure of Time, on a second that of Fame, on others, Honour, Nobility, Virtue, and Glory. Had the salaries of singers been at this time equal to the present, the support of such expensive and puerile toys, would have inclined the managers to enquire, not after the best, but the cheapest vocal performers they could find; as splendid ballets often oblige them to do now; and it is certain, that during the 17th century, the distinctive characteristic charm of an opera was not the music, but machinery. The French established musical dramas in their court and capital during the rage for mythological representations, to which they have constantly adhered ever since; and when they are obliged to allow the musical composition and singing to be inferior to that of Italy, they comfort themselves and humble their adversaries by observing, that their opera is, at least, a fine thing to see: "c'est au moins un beau spectacle, qu'un opera en France."

MACHINERY, in *Mechanics*, may be considered as the operative and moving parts of machines; it is, however, very generally, though perhaps improperly, applied to include all the parts of machines, fixed as well as moving, and in this view may be considered as the instruments or parts by which the principles of mechanics are carried into execution, and rendered applicable to all the purposes of arts and manufactures.

The denomination machine is now vulgarly given to a great variety of subjects that have very little analogy by which they can be classed with propriety under one name: we say a travelling machine, a bathing machine, a copying machine, a threshing machine, an electrical machine, &c. &c. The only circumstances in which all these agree, seem to be, that their construction is more complex and artificial than the utensils, tools, or instruments which offer themselves to the first thoughts of uncultivated people; they are more artificial than the common cart, the bathing tub, the flail, or the glass tube which first discovered the phenomena of electricity. In the language of ancient Athens and Rome, the term was applied to every tool by which hard labour of any kind was performed; but in the language of modern Europe, it seems restricted either to such tools or instruments as are employed for executing some philosophical purpose, or of which the construction employs the simple mechanical powers in a conspicuous manner, so that their operation and energy engage the attention. It is nearly synonymous, in our language, with *engine*; a term altogether modern, and in some measure honourable, being bestowed only, or chiefly, on contrivances for executing work in which ingenuity and mechanical skill are manifest. Either of these terms, machine or engine, is applied with impropriety to contrivances in which some piece of work is not executing on materials, which are then said to be manufactured. A *travelling* or *bathing* machine is surely a vulgarism.

A machine or engine is, therefore, a tool, but of complicated construction, peculiarly fitted for expediting labour, or for performing it according to certain invariable principles: and we should add, that the dependence of its efficacy or mechanical principles must be apparent, and even conspicuous.

The contrivance and erection of such works constitute the profession of the engineer; a profession which ought by no means to be confounded with that of the mechanic, the artisan, or manufacturer. It is one of the *Artes liberales*; as deserving of the title as medicine, surgery, architecture, painting, or sculpture. Nay, whether we consider the importance of it to this flourishing nation, or the science that is necessary for giving eminence to the professor, it is very doubtful whether it should not take place of the three last named, and go *pari passu* with surgery and medicine.

In the language of our practical mechanics, the terms *machine*, *engine*, and *mill*, are used without a proper distinction of the classes of machinery to which they should in strictness be applied. All these denominations are alike the practical applications of the science of mechanics, and consist only of different combinations of the mechanical powers. Though the combinations and modifications which the ingenuity of mankind is constantly producing are endless, still it is possible, by a proper classification, to arrange them under their proper terms, to avoid the confusion which at present prevails amongst those of our ingenious countrymen, who have laboured to improve the arts dependent on mechanics, without troubling themselves to fix upon the most precise language in which to express their ideas. If we might presume to decide upon a proper definition of these words, which has not hitherto been done, we should advise that the term machine be used as generic, and applied to any mill, engine, instrument, or apparatus having moving parts. That machinery should also be used as a general term, signifying the moving and operative parts of any machine or engine whatever, and its synonymous term mechanism be applied to the most delicate machinery, such as the parts of watches and mathematical instruments, or to the most delicate parts of any other machine, as the machinery of a flour-mill, or sawing-mill; the mechanism of a clock, watch, orrery, &c.

Let the term *engine* be restricted to such machines as have some relation to hydraulics or pneumatics, or, in short, where their operations depend upon, or actuate fluids; as a steam engine, a water engine, pumping engine, blowing engine, pressure engine, and fire extinguishing engine.

Mill should be applied to large and powerful compound machines, or systems of machines: including their first mover in the term; as a cotton mill, which contains a vast number of different machines, and also the water wheel, or steam engine, which actuates them all; so likewise, an iron mill, copper mill, rolling mill, grinding mill, logwood mill, wooded mill, &c. &c.

Grain mill, or *flour mill*, is, in some degree, an exception to our definition, because in the early stages of society it was the only mill in use, and hence the term became particularly attached to it; and any machine for grinding or reducing to powder is called a mill, as a coffee mill, bark mill, colour mill, malt mill, &c. though, in strictness, these should be called machines.

In this classification, we have studied to infringe as little as possible upon the distinctions which have been made by custom, and confirmed by the usage of mechanics themselves, though not invariably, for they have dividing engines, cutting engines, and many others which should be machines.

MACHINERY.

The practical application of mechanics to the construction of machinery, is a subject of the utmost importance to the welfare of our country, depending so materially as it does upon commerce, which is derived chiefly from our manufactures; and these owe the pre-eminence they have over other nations to the general introduction of machinery, which has taken place within these forty years, to abridge manual labour in every department, and in every trifling operation: it is to this source we must look for the increase of property of every description, as the introduction of every machine is a real creation of all the work it will perform, without the addition of farther increase of human labour. An idea is very generally entertained, that machinery is prejudicial to the interest of mankind, as far as it tends to diminish the value of that labour by which the lower classes of society can alone purchase the means of subsistence: this idea is, however, founded on error, as applied to any supposed injury society in general can sustain, though individuals whose labours are superseded by machines, will suffer inconvenience for a time, yet it is only for a time, and so long as they, or others more intelligent, shall discover a new channel for the exertion of their industry. As machines tend to increase the quantities of those luxuries and necessities of life which mankind are so anxious to obtain, it only requires that an equitable division of these benefits should be made to obviate every objection, and really improve the condition of all classes; a retrospect of the last forty years shews the truth of this observation, for though so many machines have been employed in all trades and manufactures as probably to do more work than the whole population could do previous to that period, yet the value of human labour has, notwithstanding, increased in the same proportion as other articles have advanced in price.

We shall, in this article, enter into some general observations upon the construction of machinery, and particularly point out such contrivances as seem applicable to other purposes than those for which their inventors have employed them; and we shall give, as examples of practical machinery, a description of the famous block machines at Portsmouth, which contain many new contrivances. We were unable to introduce these under the article *Block*, as the machines were not erected at the time that article was printed.

The grand object of all mechanism, or machinery, is to convey and modify the motion of the first mover of the machine, and communicate it in a proper manner to the subject to be operated upon: thus, the slow rotative motion of a water-wheel is, by the machinery of cranks, levers, and toothed wheels, converted into a rapid reciprocating motion for working sawing machines, and the velocity of the motion is increased or diminished, as the occasion requires either great power or great speed. In like manner, the rectilinear motion of the piston rod of a steam engine is, by the machinery of parallel levers, working-beam, connecting-rod, crank and fly-wheel, converted into a rotative motion; and this motion can again, by the machinery of wheel-work, be adapted, either in velocity or power, to work grinding-stones, circular saws, threshing-mills, and other similar machines which require great velocity; or fluting-mills, boring machines, rasping machines for logwood, lead-pipe drawing machines, &c. which require great power to give them motion, and are, therefore, performed with a less velocity. Machinery is, therefore, the organs by which motion is altered in its velocity, its period, and direction, and thus adapted to any purpose. All machinery will be found, upon minute investigation, to be only modifications of the six mechanical powers: the greatest number will be found to

consist chiefly of parts which have a motion of rotation round fixed axes, and derive all their energy from levers virtually contained in them: thus the pulleys, wheel and axle, are only modifications of the lever, and the screw is compounded of the lever with a variety of the inclined plane or wedge, so that the number of mechanical powers may be reduced to two, which assume an infinite variety of forms and motions. The theory and manner of calculating their effects will be found under *MECHANICS*.

In contriving any machinery, the engineer should always remember that nothing contributes more to the perfection of a machine, especially if it is massive and ponderous, than great uniformity of motion. Every irregularity of motion wastes some of the impelling power; and it is only the greatest of the varying velocity which is equal to that which the machine would acquire if moving uniformly throughout; for while the motion accelerates, the impelling force is greater than what balances the resistance then actually opposed to it, and the velocity is less than what the machine would acquire if moving uniformly; and when the machine attains its greatest velocity, it attains it because the power is then not acting against the whole resistance. In both of these situations, therefore, the performance of the machine is less than if the power and resistance constantly bore the same relation to each other, in which case it would move uniformly.

Every attention should, therefore, be given to this, and we should endeavour to remove all cause of irregularity through the whole machine. There are continual returns of strains and jolts from the inertia of the different parts acting in opposite direction. Although the whole momenta may always balance each other, yet the general motion is hebling, and the points of support are strained. A great engine, so constructed, commonly causes the building to tremble; but when uniform motion pervades the whole machine, the inertia of each part tends to preserve this uniformity, and all goes smoothly. It is also deserving of remark, that when the communications are so contrived, that the uniform motion of one part produces uniform motion to the next, the pressures at the communicating points remain constant or invariable. Now the accomplishing of this is generally within the reach of mechanics, and the engineer should adapt his machinery to the particular case before him.

In the machinery for modifying and adapting a rotatory motion, the first which presents itself is the communication by means of toothed wheels acting on each other. This is the most general method in machinery, because it transmits the motion with certainty and accuracy, and if the teeth are properly formed, wheels, perhaps, consume less force in friction than any other method; but this is a subject understood by few mechanics. In the treatises on the construction of mills, and other works of this kind, are many instructions for the formation of the teeth of wheels, and almost every noted millwright has his own nostrums; but they are most of them defective in principle, or at least they are only correct in certain cases, which have by experiment or theory been determined, and are extremely fallacious when applied indifferently for all cases, as is the millwright's custom. An investigation of this subject, as applied to delicate mechanism, where accuracy rather than strength is the object, will be found in our article *Clock Work*, and we propose to give some further applications of these principles to wheels of large dimensions under *MILL Work*.

In the formation of the teeth of wheels, a small deviation from the perfect form is not, perhaps, of very great importance, except in cases where a very large wheel drives

MACHINERY.

drives a very small one, a case the judicious engineer should always avoid: the grand point to be attended to, is to adopt such a construction as will insure all the teeth of a wheel being precisely equal, and to make as great a number of them as the strength will admit. This will cause several teeth to be in action at once, and make the communication of the motion extremely smooth and uniform. To obtain strength in the cogs when they are made fine, the width or thickness of the wheel must be increased; and this is one of the greatest practical improvements which has been made in machinery for these last twenty years. Formerly the best engineers, such as Smeaton, directed the teeth of large cog-wheels to be four and five inches distant from each other, or *pitch*, as the millwrights term it. Such wheels always act unequally upon each other in consequence of the point of contact of the large cogs constantly altering its position, becoming alternately nearer or farther from the centre of one or other of the wheels; and this, tending to increase the acting radius of one, whilst it diminishes the other, causes their velocity and powers to vary at every cog that passes by, and the machine works by starts and jerks. The wheel-work of modern machinery is constructed with fine cogs, seldom more than one and a half or two inches pitch, and as much length of cog, or breadth of the wheel, as will make them sufficiently strong. We have seen some wheels in a large cotton mill which bore a strain equal to thirty horses' power, in which they were nine and twelve inches broad upon the face. Cog-wheels are found to work most smoothly when the teeth of the large wheel are made of hard wood, and the teeth of the small one made of cast iron, the acting surfaces being dressed or filed smooth and to the true figure. A mechanic, in contriving any machinery, should always bear in mind, that where he introduces cog-wheels, they should be as large in their diameters as is consistent with other circumstances, because this allows the teeth to be made finer in proportion to the power they are to bear, than if they were of smaller radii; and the teeth, therefore, nearer the centre: it also occasions less pressure or drift upon the centre, and the wear of the whole will be equable. Another circumstance is worth notice, and should always be attended to, where it will not interfere with more important considerations: this is, the direction in which any force is given to, and taken from, any piece of wheel-work: suppose, for instance, a water-wheel turning its axis, upon which is fixed a cog-wheel to give motion to a second wheel, for the purpose of driving any machinery; now if this second cog-wheel is applied on that side of the first cog-wheel which is ascending, it will be opposite to that side of the wheel which is loaded with water, and is consequently descending. In this state the gudgeons of the water-wheel will have to bear (in some cases) double the strain of the power of the machine: because the power, which is the weight of the water, is applied on one side the centre of the wheel, and is taken off by turning the second cog-wheel on the other side: the centre, or fulcrum, therefore, bears the whole power, and also the re-action to that power, in addition to the weight of its own parts; in the same manner as the fulcrum of a steelyard or balance beam bears the whole of the weight suspended from either end, and its own weight also. On the other hand, suppose the second wheel applied on the descending side of the water wheel, this being on the same side of the centre, the pressure thereon will be far less than the power of the machine. In some cases (but not in a water-wheel), by the proper arrangement of the wheel work, the power may be made to operate to lift the centres, and thus in part relieve them from the weight of the wheel, so as actually to diminish the pressure of

friction of the pivots, when, by a contrary application, it would have increased it in the same degree. Similar advantages will attend the precaution of adapting the positions of different wheels upon their shafts to the different weights or strains they have to bear, so that the gudgeons at the two ends of any shaft may have an equal drift or pressure upon them. This will cause them to wear equally, and to have less friction, because they may be made smaller than where no such care is taken, still having sufficient strength. It is accomplished by considering the drift or pressure upon the centre of every wheel upon any axis, and placing the two gudgeons or pivots of the axis at a distance from each of the wheels, proportionate to the drift upon its centre. Thus, suppose a shaft has a cog-wheel fixed upon it, and a small wheel or pinion also fixed upon it at some distance from the wheel, the power is given to the axis by wheel-work operating upon the teeth of the pinion, and the re-action to this power is given by some machinery which the teeth of the large wheel actuates. In this case the drift on the centre of the pinion will be very considerable, because the power is applied near the centre of the axis; but the wheel transmitting the power at a greater radius, will, perhaps, have much less drift on its centre (the proportion depending in some degree upon the direction in which the power and re-action are applied, as stated in our last observation): if this is the case, the gudgeon at that end of the shaft, where the pinion is placed, should be lengthened out, so as to give the bearing point at a greater distance from it than the wheel, which should have its gudgeon placed much nearer to it, because less strain is to be borne. By this means the drift upon the two ends of the shaft will be equally divided between them: and though this proportion of the centre cannot be always accomplished without inconvenience, the engineer should always have it in view; and then, where it is not practicable, he should attain the same end, by apportioning the strength or diameter of the gudgeons to the relative strains they have to bear.

An endless belt or strap is a very general method of transmitting rotatory motion: it is usually employed in cases where a very quick motion is to be created, and the re-action to be overcome is nearly equable. In such cases it has the advantage of wheel-work from its simplicity and the ease of its motion. Some curious properties belong to the endless strap, *viz.* that the pulley or rigger it works upon must be largest in the middle, that is, the diameter must be greater in the middle of the pulley than at the edges, because the strap always rides on to the largest diameter of the pulley, and if this is not in the centre it will slip off at one side. It is not easy to give any satisfactory explanation of this fact, nor of another, that if, by accident, one of the pulleys is stopped while the strap is urged round by the motion of the other, it instantly flies off its pulley, unless the edge of the pulley should be much wider than the strap. This property is a great recommendation of it for some purposes, such as threshing mills, flour-dressing machines, lathes, cotton machines, &c. where any thing accidentally stopping the machines would destroy them if driven by wheel-work, but the strap slips round, and very soon comes off, so as to avoid all further danger. Belts of *gan-mah*, such as are used for saddle girths, are sometimes used instead of leather straps, though these are undoubtedly preferable. The strap should be dressed to an equal thickness and breadth throughout, and the ends very neatly joined; that is, of the same thickness there as at every other part. It is sometimes done by sewing, but the best method is by gluing them together, with a glue compounded of Irish glue, munglass, ale grounds, and boiled linseed oil. The two ends being tapered away and overlapped

overlapped are united with this cement, and will be as flexible as any other part, but so strong that it will tear to pieces in any part rather than at the joint. A tool for equalizing the thickness and breadth of the straps for belts is described in the Transactions of the Society of Arts, vol. xxviii. p. 192, invented by Mr. Aubrey. They will by this means be rendered very correct, for nothing can be more unpleasant in machinery than the joint and thick places in the endless straps jerking over the riggers, and causing a violent drift upon the centres every time by the increased tension of the strap.

A mechanic, in calculating any extensive piece of machinery which is to depend upon straps for the communication of its motions, particularly if they are of great length to convey their motion to a considerable distance, and have much strain upon them, should always consider that such machinery will lose some of its velocity; that the wheels, which are turned by straps, will never make quite so many revolutions as they ought to do from a calculation of their diameters. This is generally supposed to arise from the strap slipping, in some degree, upon the surface of the wheels it passes over, but we are inclined to suspect that it arises from another cause which has not been investigated, viz. the elasticity of the strap: for instance, suppose that the distance between two wheels connected by a strap is ten feet, and that the strain upon the strap is such as to stretch or extend it two inches in that length on the side which bears the strain (called by mechanics the leading side), on the other, or returning side, there will be no strain, and therefore the strap will return to its original length. In such a case the wheel which is driven will lose in its motion two inches in every ten feet, because the strap gives out that quantity in leading to the wheel, but takes it up again in returning, as soon as the strain is removed from it.

Small machines are sometimes turned by a catgut band, the ends of which are united by a small steel hook and eye, the hook being fastened at one end and the eyes at the other. They are made with tubes, for the reception of the ends of the band, which are tapped with a screw withinside, and the band being tapered and screwed into the tube holds very fast. But to prevent it drawing out, a small quantity of rosin should be applied to the end of the band which projects through the tube, and a hot wire being touched to it fuses and hardens the end, that it will never draw out of the tube. This method is constantly used in small lathes, and works very neatly. The pulleys for a catgut-band should always be cut with a sharp angular groove, for the reception of the band, and it should not touch the bottom of it, or it will be liable to slip. For the same reason, the pulleys are best made of wood, because metals soon acquire a polish, which prevent the band holding firmly upon it. The wood should be cut with its grain across the direction of the band, that every part of the circumference may be of a similar texture.

Endless chains are sometimes used to communicate motion of wheels, and frequently cogs are formed on the wheels to be received into the links of the chains. This method is very practicable on particular occasions, and though it has not advantages to put it in competition with cog-wheels acting upon each other when they can be applied, it is in many instances a valuable resource to the engineer to convey motion to some distance when it requires to be accurate, and where it would injure the operation of the machine if any motion was lost by the slipping of bands. In making such chains the greatest care is necessary to have all the links precisely of one length, and the cogs very accurately fitted to them, or a great friction will be caused by the cogs

forcing themselves into spaces not exactly situated to receive them. The best way is to make the links in the manner of watch or clock chains, with iron plates, and holes drilled through them at equal distances, to receive cross pins upon which the cogs are to act. By this means the lengths may be made far more accurately than by bending the iron in the manner of common chain links.

Mr. Nicholson has described a spinning-wheel for children, at a charity-school, in which a large horizontal wheel, with a slip of buff leather glued on its upper surface near the outer edge, drove twelve spindles, at which the same number of children sat.

The spindles had each a small roller, likewise faced with leather, and were capable, by an easy and instantaneous motion, of being thrown in contact with the large wheel at pleasure; each child, therefore, could throw her own part of the apparatus into work, or cause it to stop as often or as long as she pleased.

The winding bobbins for yarn at the cotton mills operate on the same simple and elegant principles, which possess the advantages of drawing the thread with an equal velocity, whatever may be the quantity of the bobbins, and cannot break it. The same mode of communication has been adopted in large work by Mr. Taylor, of Southampton, in his saw mills. In this the wheels acted upon each other by the contact of the end grain of wood instead of cogs. The whole made very little noise and wore very well: it was in use nearly twenty years. There is of consequence a contrivance to make the wheels bear firm against each other, either by wedges at the socket or by levers. This principle and method of transmitting mechanic power certainly deserve attention; particularly as the customary mode by means of teeth requires much skill and care in the execution; and after all wants frequent repair. We have seen it applied to a threshing machine, a small wheel on the threshing drum being applied in contact with the large wheel which gave motion to it, and a pressure sufficient to make it turn the machine was given by loading the socket for the spindle of the drum with a considerable weight. The same principle is capable of communicating motion with great accuracy when no force is required, as will be seen on a perusal of Mr. Troughton's ingenious method of dividing astronomical instruments. See GRADUATION.

The construction of bearings, pivots, gudgeons, or centres, of spindles, as they are indifferently termed, is a most important point; these parts being the principal seats of that friction which is the destruction of all machinery. Pivots are always made of iron or steel, both because these substances are better adapted for rubbing surfaces, and that their strength admits the pivot being as small as possible; the bearing, or bed to receive the gudgeons or pivots, should be of a softer metal, as brass, tin, or zinc, and kept well supplied with oil when at work. Hardened steel is a most admirable substance for pivots, which have a great strain to bear, and a rapid motion. The bearing or bed may also be made of the same material, and is the only instance where two bodies, having friction against each other, can with propriety be made of the same substance: for it is found, that where iron or soft steel surfaces are worked with a friction against parts of the same substances, the friction and abrasion are far greater than when a softer material, as brass, tin, hard wood, ivory, horn, &c. is used. The great difficulty of making hard steel pivots to spindles is the only reason they are not generally used; but there are some cases, in which nothing else can be employed: where steadiness and accuracy of motion are required, and great velocity at the same time. To obtain this accuracy, it is necessary that the

MACHINERY.

pivot should be fitted, and kept in accurate contact with the interior surface of its socket or pivot-hole, and this will present a sufficient access of oil, to prevent any other spindle, than one of hardened steel, from burning or heating by the friction, when in rapid motion; and the expansion occasioned by this heat increases the pressure and the friction, till the pivot becomes fixed in its socket, and will rather twist off than turn round in it. The spindle for a turning lathe must always be of hard steel; and even then, a failure of the supply of oil for a moment, will cause it to burn into the collar. Circular saw-spindles are frequently burnt in the same manner; their motion being very quick.

The best form of a gudgeon or pivot for a spindle, is that of a cylinder, with a flat shoulder, to prevent it from shifting in its position endways. This form will bear most fairly and steadily; but it is necessary that the socket, or brass which contains the pivot, should be made in two halves, and put together with screws, that the halves may be screwed closer as the socket enlarges by wearing; but as this is only an imperfect method, because the pivot can never fit accurately after having been worn, a conical form is used for the pivots of axes requiring great accuracy, as these may be always made to fill their sockets, by pressing the cone farther into its socket. The cone is used in many turning lathes, whilst others are made very nearly cylindrical, with a shoulder; and as the collar is of hard steel, they do not wear in any sensible degree. Their advantage over the cone is, that they have no drift endways upon the opposite centre, as the cone has; though this is of slight importance in small machinery. In heavy works, such as the gudgeons of water-wheels, a conical figure would be highly improper, and has no advantage to recommend it; as such gudgeons seldom have any brass screwed down over them, their own weight being sufficient to keep them down, and they always fit true as they wear away. The most accurate and simple of all pivots is that which is similar to a piece of work, while turning in a lathe; the axis having a small hole made in each end of it, and the supports formed by sharp conical points, received into the holes; and one of them must be adjustable by a screw, to make it always fit the length of the spindle. It is usual to make the conical points on the ends of two screws, either of which may then be adjusted. The same thing may be accomplished by making conical points at the ends of the spindle, and forming the holes for its reception in ends of the two fixed screws, which can at all times be screwed up as the parts wear. It is the most perfect of all methods, but is not adapted to bear any great strain, because the screws will get loose, and all the objections to the conical spindle apply to it.

The pivot at the lower end of a vertical shaft, which has a great weight to sustain, as in a heavy horse-wheel, is very properly made of a hemispherical figure, and received into a proper cavity. A cylindrical pivot, having a flat end, is frequently used for large and heavy upright axes; but it is difficult to keep oil supplied to them, as the great weight presses it out from between the acting surfaces, and the gudgeon burns. To avoid this, some mechanics make a cleft across the lower face of the gudgeon, exactly in the manner of a screw-head. This getting full of oil, is constantly supplied to the acting surfaces.

We have seen an horizontal windmill, having a vertical axis 100 feet high, with sails and wheels of immense weight, all bearing upon one pivot. This was with the greatest difficulty kept in order; and it was necessary to keep a small stream of cold water always running into a pan, which surrounded the gudgeon, to keep it cold. This method of

watering, instead of oiling, a gudgeon is also used in paper-mills; but it cannot be recommended as a good method.

Friction-rollers are frequently used for supporting gudgeons, and, if made with great care, have the least friction which can be conceived; but they are liable to get out of order, if not made with extreme accuracy. See *MILL-Work*.

A great number of machines, depend upon reciprocating motions, such as pump-mills, saw-mills, &c. Where the first mover has a circular motion, as a water-wheel, the reciprocating movement will be most conveniently produced by means of a crank; because it commences the change of motion by degrees, and does not suddenly urge the parts into motion in a contrary direction; nor suddenly check the movement again, but effects both changes without violence. It is proper, in such cases, to regulate the motion of the first mover by a fly-wheel, otherwise the resistance of the work, at the instant of the change of motion, is so small, that the machine would accelerate in that period, and then be checked again. The same may be accomplished by having several of the reciprocating movements and these act alternately, that when one requires the most power, the others take the least, so as to equalize the resistance to the first mover, and make the motion uniform. All reciprocating machines labour under great disadvantages, from the circumstance that a great mass of matter must be put in motion, and this motion destroyed again. Thus, in a single pump forcing water through a great height of pipes, the column of water is, at every stroke the pump makes, put in rapid motion, which is wholly lost during the return of the pump-bucket for another stroke, when fresh impetus must be given to the water: now by applying a double acting pump, or two or three pumps acting at intervals, and the water regulated by an air-vessel, the motion will be very easy, because the column of water will be in constant motion through the pipes, and the momentum once given to it will continue as long as the machine is at work, instead of requiring a repetition of it at every stroke.

In every machine, the action of the moving power is transferred to the working point, through the parts of the machinery, which are material, inert, and heavy; or, to describe it more accurately, before the necessary force can be exerted at the working point of the machine, the various connecting forces must be exerted in the different parts of the machine: and in order that the working point may follow out the impression already made, all the connecting parts or limbs of the machine must be moved in different directions, and with different velocities. Force is necessary for thus changing the state of all this matter, and frequently a very considerable force. Time must also elapse before all this can be accomplished. This often consumes, and really wastes, a great part of the impelling power. Thus, in a crane worked by men walking in a wheel, it acquires motion by slow degrees; because, in order to give sufficient room for the action of the number of men or cattle that are necessary, a very capacious wheel must be employed, containing a great quantity of inert matter. All of this must be put in motion by a very moderate preponderance of the men: it accelerates slowly, and the load is raised. When it has attained the required height, all this matter, now in considerable motion, must be stopped. This cannot be done in an instant, with a jolt, which would be very inconvenient, and even hurtful: it is therefore brought to rest gradually. This also consumes time. Nay, the wheel must get a motion in the contrary direction, that the load may be lowered into the cart or lighter; and this can only be accomplished by degrees. Then the tackle must be lowered down again.

for another load, which also must be done gradually. All this wastes a great deal both of time and force, and renders a walking-wheel a very improper form for the first mover of a crane, or any machine whose use requires such frequent changes of motion. The same thing obtains, although in a lower degree, in the steam-engine, where the great beam and pump-rods, sometimes weighing many tons, must be made to acquire a very brisk motion in opposite directions, twice in every working stroke. It operates in a greater or a less degree, in all engines which have a reciprocating motion in any of their parts. Pump-mills are of necessity subjected to this inconvenience. In the famous engine at Marly, about $\frac{1}{2}$ th of the whole moving power of some of the water-wheels is employed in giving a reciprocating motion to a set of rods and chains, which extend from the wheels to a cistern about three-fourths of a mile distant, where they work a set of pumps: thus the engine is, by such injudicious construction, a monument of magnificence, and the struggle of ignorance with the unchangeable laws of nature. In machines, all the parts of which continue the direction of their motion unchanged, the inertia of a great mass of matter does no harm; but, on the contrary, contributes to preserve the steadiness of the motion, in spite of small inequalities of power or resistance, or unavoidable irregularities of force in the interior part. But in all reciprocations, it is highly prejudicial to the performance; and, therefore, constructions which admit such reciprocation without necessity, are avoided by all the intelligent engineers.

In many machines, but generally in small works, what are called hearts, camms, snails, excentric wheels, &c. are a very excellent method of producing slight reciprocating movements to levers. From the rotatory motion of an axis, they have the great advantage of admitting any modification of the motion, to act suddenly or gradually, in either direction, at the pleasure of the maker. This is done, by wheels of a particular form, fastened upon an axis, and levers applied in contact with their circumferences, which receive a motion in proportion as the different radii of the wheels alter their lengths; and if, at any point of the motion, the lever is to be in a state of rest, the periphery of the wheel is, during that period, made a circular arc, and concentric with the axis. From the facility of producing any motion whatever by camms, it is an universal method, and applicable to all subjects; but still has objections, which will induce the engineer to neglect it in those instances, where any other movement will answer the same purpose. These objections are the great friction, and wear of the camms, which soon unfit them for accurate motion: this may in some measure be obviated by applying rollers in the ends of the levers, to receive the contact of the camm. Another objection is, that the camm is unfit for producing a double motion, because a spring or weight must be introduced to return the lever, and always keep it in contact with the camm. Now if this spring is only used to return the lever, it will operate very well; but if it is made so strong as to effect any operation of the machine, the friction will be great, and be a serious objection to the use of camms.

The principles of these movements, and practical directions for constructing camms for any kind of movement, is fully explained in our article *DIAGONAL Motion*, which renders it unnecessary to enlarge upon the subject in this place. Camms are used on a large scale in rolling-mills, for working the shears with which large iron bars are clipped into lengths. They are also employed in the machine for punching holes through the iron plates for boilers, weaving machines, &c.: and are in common use in the blowing ma-

chine used in iron forges; but it is a very injudicious application, and a common crank would be much better.

We once with great pleasure contemplated a very complicated machine, in which were many reciprocating parts necessarily operating only whilst moving in one direction; in the other, they had merely to return to repeat their operations. To produce this reciprocation, the inventor applied a crank, which was caused to revolve by the action of a pair of elliptical cog-wheels, each balanced on an axis passing through one of its foci. In this construction, the motion of the driven wheel and the crank it carried, was exceedingly variable, but by equal increments of alternate acceleration and retardation. Thus when the long radius of the first wheel was operating, it met the shortest radius of the other, therefore giving it and also the crank a rapid motion: in this state, the crank was returning to repeat its stroke, and with a quick stroke; but by the time it had completed half a revolution, the action was reversed, the short radius of the first wheel acting upon the long radius of the second, which was therefore with its crank at the slowest point of its movement: but the decrease of the motion, from the quickest to the slowest point of its revolution, being effected by equal increments, gave no shock to the machinery. The crank was of course, during the slow half of its movement, performing its work; and in the quick period, returning to fetch its stroke. By this judicious arrangement, the resistance to the first movement was very nearly equable: for when it had work to perform, the wheel-work gained a power upon the working point; but in returning, it caused it to urge the working point with such an increased velocity, as in some degree counterbalanced the diminished resistance: but in this, no loss was occasioned, because this increased velocity shortened the period of inaction hastening the return to a situation for repeating its operation.

These elliptical wheels are, in the hands of an able mechanic, a very useful contrivance, but they have not been much used in machinery, from the difficulties of forming their teeth with precision. In the *COMETARIUM*, (see that article,) they are introduced to represent the elliptic motions of comets, and we have seen two instances of their being used in large machines, where they operated with as much facility as circular wheels. It is to be observed, that a small excentricity of the ellipse, consequently a slight deviation from the circular figure, will produce a great inequality of their motion, because the increase of the acting radius of one wheel, is attended with a correspondent decrease of the other, so that to produce almost any differences of motion which can be required in practice, the excentricity of the wheels will be such as can easily be accomplished, and as will work with each other smoothly and accurately. When heavy stampers are to be raised in order to drop on the matter to be pounded, the wipers, by which they are lifted, should be made of such a form that the stamper may be raised by an uniform pressure, or with a motion almost imperceptible at first. If this is not attended to, and the wiper is only a pin sticking out from the axis, the stamper is forced into motion at once. This occasions a violent jolt to the machine, and great strains on its moving parts and their points of support: whereas, when they are gradually lifted at first, the inequality of defultory motion is never felt at the impelled point of the machine.

We have seen pistons of pumps moved by means of a double rack on the piston rod: a half wheel takes hold of one rack and raises it to the required height. The moment the half wheel has quitted that side of the rack, it lays hold of the other side and forces the piston down again. This has been proposed as a great improvement, by correcting the

the unequable motion of the piston, moved in the common way by a crank motion; but it occasions such abrupt changes of motion, that the machine is shaken by jolts. Indeed, if the movements were accurately executed, the machine would be soon shaken to pieces, if the parts did not give way by bending and yielding. Accordingly we have always observed that this motion soon failed, and was changed for one that was more smooth: a judicious engineer will avoid all such sudden changes of motion, especially in any ponderous part of a machine.

When several stampers, pistons, or other reciprocal movers are to be raised and depressed, common sense teaches us to distribute their times of action in an uniform manner, so that the machine may always be equally loaded with work. When this is done, and the observations in the preceding paragraph attended to, the machine may be made to move, almost as smoothly as if there were no reciprocations in it. Nothing shews the ingenuity of the engineer more, than the artful, yet simple and effectual contrivances, for obviating those difficulties that unavoidably arise from the very nature of the work to be performed by the machine, or in the power employed to actuate it.

In the contrivance of machinery, an engineer must not be tied down by too many inviolable maxims, because those contrivances which are the most improper in some situations will be the best of all in other cases. There is great room for ingenuity and good judgment in the management of the moving power, when it is such as cannot immediately produce the kind of motion required for effecting the purpose. We mentioned the conversion of the continued rotation of an axis into the reciprocating motion of a piston, and the improvement which was thought to have been made on the common and obvious contrivance of a crank, by substituting a double rack on the piston rod, and the inconvenience arising from the jolts occasioned by this change. We have been informed of a great forge, where the engineer, in order to avoid the same inconvenience arising from the abrupt motion given to the great sledge hammer of seven hundred weight resisting with a five-fold momentum, formed the wipers for lifting it into spirals, which communicated motion to the hammer with scarcely any jolts whatever: but the result was, that the hammer rose no higher than it had been raised in contact with the wiper, and then fell on the iron bloom, with very little effect. The cause of its inefficiency was not guessed at; but it was removed, and wipers of the common form were put in place of the spirals.

In this operation the rapid motion of the hammer is absolutely necessary; it is not enough to lift it up, it must be raised up so as to fly higher than the wiper lifts it, and to strike with great force the strong oaken spring which is placed in its way. It compresses this spring, and is reflected by it with a considerable velocity, so as to hit the iron as if it had fallen from a great height: had it been allowed to fly to that height it would have fallen upon the iron with somewhat more force (because no oaken spring is perfectly elastic); but this would have required more than twice the time.

In employing a power which of necessity reciprocates, to drive machinery which requires a continuous motion (as in applying the steam engine to a cotton or corn grinding mill), there also occur great difficulties. The necessity of reciprocation in the first mover wastes much power, because the instrument which communicates such an enormous force must be extremely strong, and be well supported. The impelling power is wasted in imparting, and afterwards destroying a vast quantity of motion in the working beam. The skilful engineer will attend to this, and do his utmost

to procure the necessary strength of this lever, without making it a vast load of inert matter. He will also remark, that all the strains on it, and on its supports, are changing their directions in every stroke. This requires particular attention to the manner of supporting it: if we observe the old steam engines which have been long erected, we see that they have uniformly shaken the building to pieces. This has been owing to the ignorance or inattention of the engineer in this particular; they are much more judiciously erected now, experience having taught the most ignorant that no building can withstand their desultory and opposite jolts, and that the great movements must be supported by a frame work of wood or iron, independent of the building of masonry which contains it. The gudgeons of a water wheel should never rest on the wall of the building; it shakes it, and if set to work soon after the building has been erected, it prevents the mortar from taking firm bond, perhaps by shattering the calcareous crystals as they form.

When the engineer is obliged to rest the gudgeons in this way, they should be supported by a block of oak laid a little hollow: this softens all tremor, like the springs of a wheel carriage. This practice would be very serviceable in many other parts of the construction. It will frequently conduce to the good performance of an engine, to make the action of the resisting work, unequable, and accommodated to the inequalities of the impelling power. This will produce a more uniform motion in machines, in which the momentum of inertia is inconsiderable. There are some beautiful specimens of this kind of adjustment in the mechanism of animal bodies.

In many compound machines it is of consequence to be able to detach part of the movements while the others continue in motion. Thus in cotton-spinning machines, it is necessary to be able to call off or stop any spindle at pleasure, without disturbing the rest; and in a large mill containing many machines, it is essential that any one may be released without interruption to the first mover. Such contrivances are called coupling or clutch-boxes: they are effected in various ways, some of which are detailed under COUPLING-BOX. But we wish here to describe a recent improvement, very generally adopted in cotton and woollen mills; the object of which is to avoid a jerk being given to any machine when it is put in action, from its being suddenly urged from a state of rest to a state of motion: for if the movement is to be rapid, nothing can be more destructive to the machine than the violence of the shock it receives from the common clutch-box. To avoid this, the arm which gives motion to the machine when the clutch of the running spindle is engaged with it, is not fixed fast upon the spindle, but is made in two halves screwed together upon a circular part of the spindle, and pinched upon it to fast by the screws, that it will have sufficient friction to turn the machine round in the ordinary course of its work, but slips round upon the spindle, if the resistance is greater than this friction, which thus becomes the measure of the power dealt out to the machine.

Suppose a machine of this kind at rest, the clutch is turned by the first mover with a considerable velocity, and is suddenly connected with the arm above described: now it requires some time (independent of any resistance or work of the machine) to put its parts in motion. In this time the arm slips round upon the spindle, but the friction acts constantly, and with an equal force upon the machine to turn it round. It commences its motion, which gradually accelerates, until it arrives at the same velocity as the driving spindle, and then the slipping of the box ceases, and the

machine proceeds in an uniform manner: still the box is a very useful provision in case of any accident happening to the machine to stop it, by any thing getting into its movements: the box then slips round without breaking the works. All machinery, which is exposed to the chance of great violence, should be provided with some equivalent contrivance, which permits the movement to slip when the machine is overloaded and would otherwise be broken. An instance of this will be seen in the *Dressing Engine*; see that article. The same effect may be produced by conical wheels fitting into each other, in the manner of a valve and its seat. One of them being fixed to each spindle, will, when they are jambed into each other, communicate the motion, but permits it to slip if overloaded. A very ingenious application of this will be found, in the mortising machine of the block machines at Portsmouth (see *Machinery for manufacturing Ships' Blocks*), and another judicious application of it under *Loose-wood Mill*.

Many other contrivances are in use for detaching or uniting motions at pleasure. In cog-wheel, the supports for the gudgeons are sometimes fitted up so as to be moveable, that the wheels can be separated to such a distance as to relieve each other's teeth. At other times one of the wheels is fitted on a round part of its axis, and united with it at pleasure by a clutch-box. Thus the wheels are always in motion, but one of them can be detached at pleasure from its axis, on which it slips freely. Bevelled cog-wheels are easily disengaged, by suffering the axis of one to move a little endways, and then their teeth are separated.

Wheels turned by flaps are readily connected, or cast off, by removing the flap, but this is not easily done while the wheels are in motion; though some dextrous workmen are able to put on the flaps when the wheels are going; but it is attended with much difficulty, and great danger, if the motion is quick, of catching the fingers in the flap. We have known an instance of a man's arm being torn away at the shoulder, by carelessness in performing this operation.

For disengaging the motion of a flap, the contrivance called the live and dead pulley is very ingenious: it consists of two pulleys placed close together upon any axis which is to receive a circular motion. The endless flap or band, by encompassing one of these pulleys, gives it a constant rotatory motion. Now one of them being fixed fast upon the spindle, and the other slipping freely round upon it, gives the means of turning or discontinuing the motion of the spindle at pleasure, by shifting the flap either upon the live or dead pulley, which, as they are exactly of the same size, and close to each other upon the spindle, is easily done. The live pulley is that which is fixed to its axis, so called from its causing life or motion to the spindle, and the machinery appended to it. The dead or idle pulley is that which slips upon its spindle; therefore, when the flap is caused to run upon it, it turns round without giving any motion to the spindle. This contrivance is extremely well adapted to give motion to small machinery, from the simplicity of its construction, and the facility with which it is put in motion or at rest. It possesses also another great advantage, viz. it occasions no sudden shock to the machinery at first starting, as it does not instantly communicate to it the full velocity. To illustrate this, suppose the flap running upon the dead pulley, and the machine therefore at rest, the leading side of the flap is in general conducted through a notch in a piece of board which is fitted in a groove, so as to have liberty of sliding in such a manner that it may conduct the flap to work upon either of the pulleys; but this is not necessary nor always attended to, for the person who attends the machine may, by the slightest pressure on the leading side flap

by his hand, cause it to shift upon the other pulley; but as this is not done instantly, it communicates the motion to the live pulley by degrees; for at first shifting, it begins upon a very narrow surface of the pulley, which is, therefore, urged into motion, but without violence to the machine, as the flap at first slips partially upon the surface of the live pulley, and this, as we have before stated, causes the flap to endeavour to escape from the pulley; but the attendant continues to press the flap on the leading side, and force it to act upon the live pulley, which having attained its full velocity, and the flap no longer slipping upon it, has no tendency to get off, unless the machine is overloaded, and then it will get off to the dead pulley. The live and dead pulley is very extensively used in cotton machinery, and is a very excellent contrivance; the only objection to it being that the bush in the centre of the idle pulley is liable to wear very loose in a short time. It is scarcely necessary to add, that the driving wheel for the flap of the live and dead pulley must be as broad on its edge as both the live and dead pulley together; indeed, it is generally a long cylindrical drum, which receives many flaps for turning different machines.

A motion is frequently required in machinery, by which a wheel or axis is made to revolve in one direction for any required time, and then at pleasure changed, so as to revolve in the other direction. Various means may be used for effecting this purpose. The most common is by means of two equal and similar bevelled or contrate wheels, situated on the same axis, and their teeth towards each other. A third bevelled wheel is applied with its axis perpendicular to the former, and its teeth engaging at pleasure with either of the two wheels, which, as they turn the same way round, and can be made to act at one or other of the sides of the third wheel, so as to turn it in either direction, as it is engaged with either of the two wheels. This movement was applied by Mr. Smeaton to a machine he invented for drawing coals from coal-pits. In this the third wheel was a trundle, and could be, by a lever, made to work in the teeth of either of the cog-wheels which were mounted upon the axis of a water-wheel, and thus turned the trundle either way at pleasure, to draw up or let down the baskets or coves, which were suspended from a drum upon the axis of the trundle. Some mechanics have constructed the contrivance in a different manner, by fitting the two wheels upon a circular part of their spindle, and suffering them to turn round freely upon it. Their teeth are always engaged with the teeth of the third wheel, and, therefore, they are always revolving in opposite directions, and either can at pleasure be connected with the axis by a sliding clutch-box, but which is not long enough to engage both at once. The axis can, by this means, be made to revolve in the direction of either wheel at pleasure, by sliding the clutch-box towards that wheel.

We have seen a very ingenious application of the live and dead pulley to this purpose, for a crane in a cotton mill, to take up and down the goods, work-people, &c. It was invented by Mr. Henry Strutt, and has been applied in his cotton mills at Belper, Derbyshire. In this machine it was necessary to have a motion which could be turned either way at pleasure, to draw up or let down the basket; but the double wheel-work above described was evidently improper, from the sudden jerk it would have given at the instant of changing the motion. It was effected in this manner: an axis which gave motion to the crane barrel, has two pair of live and dead pulleys upon it, and also a brake wheel to stop the motion, which is situated between the two pair: an endless flap is conducted to each pair, being turned by a long drum placed parallel to the axis of the pulleys, and kept in constant motion by the mill. One of these endless flaps is crossed between

between the drum and its pulleys, but the other is not, therefore one pair of the live or dead pulleys are always revolving in one direction, and the others are turning in an opposite way. Both straps are conducted through guides fixed to a sliding rail, by which the straps can be shifted both at once, sideways. When this rail is in a position that the straps are both upon their dead pulleys, the axis and brake wheel are at rest, and in this position the rail has a tendency to remain, unless forced by hand. On moving the rail one way from the quiescent point, one of the straps is thrown on its live pulley, and the spindle turns with it, winding up the basket. By moving the rail in the other direction beyond its quiescent point, this strap is shifted on to its dead pulley, and becomes inactive; but the other strap operates on its live pulley, to turn the spindle in the opposite direction, and lets down the basket. We shall describe this very useful and curious machine in its place among the cotton machinery. See MANUFACTURE of Cotton.

Logwood rasping engines, screw presses, and some other machines, require a motion to work them forwards to a certain extent, and then the direction is to be reversed to draw them back, which requires but very little power to effect it. In this case the motion may be effected by a pair of cog-wheels turning each other, and thus communicating the motion for one direction in which it is to perform the work. A couple of pulleys are fixed on the respective axes near the cog-wheels, and an endless strap connects them, but the strap is so long, that when the cog-wheels are in gear, the strap hangs slack, and does not operate: but to reverse the movement, the sockets for one of the gudgeons of the driving spindle or axis is made to shift, that the distance between the centre of the two wheels may be increased, so as to disengage the teeth of the wheels, and the strap becomes tight, and turns the wheels back; but on bringing the wheels together again, the strap becomes slack, and the wheels resume their original course.

Screws are, of all the mechanical powers, the most frequently used in machines, though not always as moving parts, being chiefly introduced for uniting and retaining the parts. They are not so constantly employed as acting movements, on account of their friction, and the trouble of making them; they are, nevertheless, a very useful agent on many occasions, and possess the advantage of accurately retaining any movement they make, and producing an extremely slow motion with ease, and, when it is required, with the most perfect accuracy. No engineer will employ screws for a rapid motion, as their friction and great wear renders them unfit for such situations. To the endless screw acting on the teeth of cog-wheels, this objection does not apply so forcibly, because the great number of teeth on which the screw operates successively, do not wear so fast as the nut of a female screw would under the same circumstances, and the friction is far less, because the screw is not enclosed all round its thread. The endless screw or worm is useful on many occasions to obtain a slow motion, which it does in a very simple manner; but, for the purpose of obtaining a quick motion, it should never be used, on account of the friction and consequent wear. This is seen in the common roasting jack.

In many situations in which moving screws are used, the same effects may be produced in the most simple and convenient manner by Mr. Bramah's method of producing and applying a more considerable degree of power to all kinds of machinery requiring motion and force, than by any means at present practised for the purpose. This method, for which, on the 31st of March 1796, he obtained a patent, consists in the application of water, or other dense fluids, to various engines, so as, in some instances, to cause them to act with immense

force; in others, to communicate the motion and powers of one part of a machine to some other part of the same machine; and lastly, to communicate the motion and force of one machine to another, though removed to a great distance from each other, and where their local situation preclude the application of all other methods of connection. The principle of this invention is the same with the hydrostatic paradox, but its various applications to useful purposes is due to Mr. Bramah. The simplest form is for a press, or machine, to raise an enormous weight to a small height: a metallic cylinder sufficiently strong, and bored perfectly smooth and cylindrical, has a solid piston fitted into it, which is made perfectly water tight, by leather packing round its edges, and other means used in hydraulic engines. The bottom of the cylinder must be made sufficiently strong, with the other part of the surface, to resist the greatest strain which can ever be applied to it. In the bottom of the cylinder is inserted the end of a small tube, the aperture of which communicates with the inside of the cylinder, and introduces water or other fluid into it: the other end of the pipe communicates with a small forcing pump, by which the water can be injected into the cylinder under its piston: the pump has of course valves to prevent the return of the water. Now suppose the diameter of the cylinder to be twelve inches, and the diameter of the piston of the small pump or injector only one quarter of an inch, the proportion between the two surfaces or ends of the said pistons will be as 1 to 2304; and supposing the intermediate space between them to be filled with water, or other dense and incompressible fluids, any force applied to the small piston will operate upon the other in the above proportion, viz. as 1 to 2304. Suppose the small piston or injector to be forced down when in the act of forcing or injecting with a weight of 20 cwt. which can easily be done by means of a long lever, the piston of the great cylinder would then be moved up, with a force equal to 20 cwt. multiplied by 2304. Thus is constructed a hydro-mechanical engine, whereby a weight amounting to 2304 tons can be raised by a simple lever, in much less time through equal space, than could be done by any apparatus constructed on the known principles of mechanics, and it may be proper to observe, that the effect of all other mechanical combinations is counteracted by an accumulated complication of parts, which renders them incapable of being usefully extended beyond a certain degree, but in machines acted upon, or constructed on this principle, every difficulty of this kind is obviated, and their power subject to no finite restraint. To prove this, it will be only necessary to remark, that the force of any machine acting upon this principle can be increased, *ad infinitum*, either by extending the proportion between the diameter of the injector and the great cylinder, or by applying greater power to the lever actuating the small pump. On this principle very wonderful effects may be produced instantaneously, by means of compressed air. Suppose a large cylinder, furnished with a piston in the same manner as before described, a globular vessel is used, made of copper, iron, or other strong material, capable of resisting immense force, similar to those used for air guns: it has a strong tube of small bore, in which is a stop-cock: one of the ends of this tube communicates with the great cylinder beneath its piston, and the other end with the globe. Now suppose the great cylinder to be of the same diameter as that before described, and the small tube equal to one quarter of an inch diameter, which is the same as the injecting pump before-mentioned for the press: then suppose that air is injected into the globe (by the common methods) till it presses against the cock with a force equal to 20 cwt. which can be done; the consequence will be, that when the cock is opened, the piston will be instantly

moved in the great cylinder, with a power or force equal to 2304 tons, and it is obvious, as in the case before-mentioned, that any other unlimited degree of force may be acquired by machines or engines thus constructed. By the hydrostatic principle, the power and motion of any machine may be transferred or communicated to another, let their distance and local situation be what they may. Suppose two small tubes or cylinders, in the inside of each of which is a piston made water and air-tight, a tube may be conveyed under ground or otherwise, from the bottom of one cylinder to the other, to form a communication between them, notwithstanding their distance be ever so great. Let this tube be filled with water, or other fluid, until it touches the bottom of the two pistons; then, by depressing the piston of one cylinder, the piston of the other will be raised. The same effect will be produced, *vice versa*; thus bells may be rung, wheels turned, or other machinery put invisibly in motion by a power being applied to either cylinder.

By these means, it is obvious, that most commodious machines of prodigious power, and susceptible of the greatest strength, may readily be formed. If the same multiplication of power be attempted by toothed-wheel pinions and racks, it is scarcely possible to give strength enough to the teeth of the racks, and the machines become very cumbersome, and of great expence. But Mr. Bramah's machine may be made abundantly strong in very small compass. It only requires very accurate execution. The hydrostatic principle on which it depends has been well known for nearly two centuries, and it is a matter of surprise that it has never before been applied to any useful practical purpose.

The application which Mr. Bramah has made of this truly valuable principle is very general: it was first applied for presses instead of large screws, for which purpose it is greatly superior in every respect. Presses being generally moved by the strength of men alone, the saving of power becomes a great object; and this it accomplishes, having no proportion of the friction of the screw, and immensely greater power. In a screw-press, it requires nearly as much labour to unscrew as to screw it up, an evidence of the enormous friction of a screw, when acting against a great pressure: but the hydrostatic-press only requires a cock to be opened to let out the water from beneath the piston, which then descends quickly, by its own gravity, or the elasticity of the subilaces under the pressure. But the greatest convenience of the hydrostatic principle is, that its power can so easily be transferred to any distance, and in any direction, by means of pipes conducted along in situations where all other means of conveying the motion would be complicated, and expensive in the extreme. Thus, in a large paper-mill, an injecting-pump may be kept in constant action by the water-mill, or steam-engine, and inject water into an air-vessel, from which pipes are conducted to presses in all parts of the mill, and by simply opening a cock at any press, any required pressure will be instantly given by the elasticity of the confined air operating on the enlarged surface of the piston of any press. The air-vessel has, of course, a safety-valve, to allow the escape of the water when the pressure becomes so great as to endanger the rupture of any of the vessels; for it is to be observed, that the power of this principle is irresistible, when the pump is worked by a mill, and will burst any vessels, without the least appearance of strain on the moving parts of the pump.

In Mr. Bramah's extensive work-shops at Pimlico, and another at Mill-Bank, London, the steam-engines which turn the laths, boring-machines, planing-machines, &c. work a small injecting-pump, as above-mentioned, and small copper pipes are laid to every part of the works, and

by cocks admitting it into various cylinders, many powerful operations are performed: it works an immense press for bending strong iron bars, or breaking cast-iron for the foundry. It moves the carriage of the planing-engine; and he has brought the methods of packing the cylinders to such perfection, that they are employed to make the most delicate adjustments in the parts of the machine. (See a full description of this in *PLANING Engine*, and also *PRESS, Hydrostatic*.) In another part of the factory, it works a crane for lifting the heaviest goods, by merely opening a cock, and lowers them down, by opening another, with the utmost safety. A very large *Flood-gate* is also raised up by two cylinders. (See that article.) It may be used for turning the bridges of canals. (See *CANAL*.) On the whole, we cannot conclude this article, without recommending the hydrostatic principle very strongly to engineers, as a method the most perfect of all others of communicating motion, which is to act only for short extents, or with great power, as it can so easily be conducted through any circuitous rout, and loses so little power by friction. The ease with which it is relieved from the action, or caused to operate in a contrary direction, is not its smallest advantage; and by means of the air-vessel the power may be accumulated while the machine is preparing for action, and then an immense power suddenly given. We have little doubt the hydrostatic-press would answer the best of any method for expressing oil. The present oil-press is described under *Oil-Mill*, and operates by a wedge, driven by repeated blows of a heavy hammer. The method is ingenious; but great part of the power is expended in friction, as is evident from the wedge requiring nothing to retain it, as it is driven, the friction over-balancing all the re-action of the substances pressed.

A motion is very frequently required in machinery for giving to any piece of wheel-work an increased or diminished velocity at pleasure. The most complete of these are the *EXPANDING Riggers* (see that article); but many other means may be employed. Thus, on two parallel spindles, which are to turn each other, place a number of wheels, increasing in size by regular steps, the smallest wheel of one spindle being opposite to the largest of the other. The same endless strap will fit any pair of them, and give a great variety of powers and velocities: the same may be effected by having a number of cog-wheels; and, instead of a strap, using an intermediate cog-wheel, which can be applied to connect any pair of the wheels at pleasure. A very ingenious application of double cones is used in a cotton-machine, called the double speeder. See *MANUFACTURE of Cotton*, also Mr. Braithwaite's *CRANE*.

It is very customary to add what is called a fly to machines. This is a heavy disk or hoop, or other mass of matter, balanced on its axis, and so connected with the machinery, as to turn briskly round with it. This may be done with the view of rendering the motion of the whole more regular, notwithstanding unavoidable inequalities of the accelerating forces, or of the resistances occasioned by the work: it then becomes a regulator. Suppose the resistance to a machine extremely unequal, and the impelling power perfectly constant; as when a bucket-wheel is employed to work one pump; when the piston has ended its working-stroke, and while it is going down the barrel, the power of the wheel being scarcely opposed, it accelerates the whole machine, and the piston arrives at the bottom of the barrel with considerable velocity; but in the rising again, the wheel is opposed by the column of water now pressing on the piston: this immediately retards the wheel; and when the piston has reached the top of the barrel, all the acceleration is undone, and is to begin again. The motion of such

such a machine is very hobbling; but the surplus of accelerating force, at the beginning of a returning stroke, will not make such a change in the motion of the machine, if we connect the fly with it; for the accelerating momentum is a determinate quantity: therefore, if the radius of the fly be great, this momentum will be attained by communicating a small angular motion to the machine. The momentum of the fly is as the square of its radius, therefore it resists acceleration in this proportion; and although the overplus of power generates the same momentum of rotation in the whole machine as before, it makes but a small and imperceptible addition to its velocity. If the diameter of the fly be doubled, the augmentation of rotation will be reduced to one-fourth. Thus, by giving a rapid motion to a small quantity of matter, the great acceleration during the return-stroke of the piston is prevented. This acceleration continues, however, during the whole of the returning stroke, and at the end of it the machine has acquired its greatest velocity. Now, the working stroke begins, and the overplus of power is at an end. The machine accelerates no more; but if the power is just in equilibrium with the resistance, it keeps the velocity which it has acquired, and is still more accelerated during the next returning stroke. But now, at the beginning of the subsequent working-stroke, there is an overplus of resistance, and a retardation begins and continues during the whole rise of the piston; but it is inconsiderable in comparison of what it would have been without the fly: for the fly, retaining its acquired momentum, drags forwards the rest of the machine, aiding the impelling power of the water-wheel. It does this by all the communications taking into each other in the opposite direction; the teeth of the intervening wheels are heard to drop from their former contact on one side, to a contact on the other. By considering this process with attention, we easily perceive that in a few strokes the overplus of power, during the returning stroke, comes to be so adjusted to the efficiency, during the working stroke, that the accelerations and retardations exactly destroy each other, and every succeeding stroke is made with the same velocity, and an equal number of strokes is made in every succeeding minute. Thus the machine acquires a general uniformity with trifling periodical inequalities. It is plain, that by sufficiently enlarging either the diameter, or the weight of the fly, the irregularity of the motion may be rendered as small as we please. It is much better to enlarge the diameter: this preserves the friction more moderate, and the pivots wear less. For these reasons, a fly is, in general, a considerable improvement in machinery, by equalising many exertions that are naturally very irregular. Thus a man, working at a common windlass, exerts a very irregular pressure on the winch. In two of his positions in each turn, he can exert a force of near seventy pounds without fatigue, but in others he cannot exert above twenty-five; nor must he be loaded with much above this in general. But if a large fly be connected properly with the windlass, he will act with equal ease and speed against thirty or even forty pounds.

If any permanent change should happen in the impelling power, or in the resistance, the fly makes no obstacle to its production in its full effect on the machine, and it will be observed to accelerate or retard uniformly, till a new general speed is acquired, exactly corresponding with this new power and resistance. Many machines include in their construction movements which are equivalent with this intentional regulation, a flour-mill for example. There is another kind of regulating fly, consisting of wings whirled briskly round till the resistance of the air prevents any great acceleration. This is a very bad one for a working machine,

for it produces its effect by really wasting a part of the moving power. Frequently it employs a very great and unknown part of it, and robs the proprietor of much work. It should never be introduced into any machine employed in manufactures, except in the instance of letting down heavy weights, where a waste or re-action to power is the object.

Some rare cases occur where a very different regulator is required, when a certain determined velocity is found necessary: in this case, the machine is furnished at its extreme mover with a conical pendulum, consisting of two heavy balls hanging by rods, which move in very nice and steady joint at the top of a vertical axis. It is well known, that when this axis turns round, with an angular velocity suited to the length of those pendulums, the time of a revolution is determined.

Thus, if the length of each pendulum be 39½ inches, the axis will make a revolution in two seconds very nearly. If we attempt to force it more swiftly round, the balls will recede a little from the axis, but it employs as long time for a revolution as before; and we cannot make it turn swifter, unless the impelling power be increased beyond all probability: in which case, the pendulum will fly out from the centre till the rods are horizontal, after which every increase of power will accelerate the machine very sensibly, as it then becomes a simple fly. Watt and Boulton have applied this contrivance with great ingenuity to their steam engine, when they are employed for driving machinery for manufactures which have a very changeable resistance, and where a certain speed cannot be much departed from without great inconvenience. They have connected this device of the balls from the axis (which gives immediate indication of an increase of power, or a diminution, or resistance,) with a cock, which admits the steam to the working cylinder. The balls flying out cause the cock to close a little, and diminish the supply of steam, if the impelling power diminishes the next moment, and the balls again approach the axis, and the rotation goes on as before, although there may have occurred a very great excess or deficiency of power. The same contrivance may be employed to raise or lower the feeding sluice of a water-mill employed to drive machinery. (See MILL.) Suppose all resistance removed from the working point of a machine furnished with a very large or heavy fly, immediately connected with the working point; when a small force is applied to the impelled point of this machine, motion will begin in the machine, and the fly begin to turn, continue to press uniformly, and the machine will accelerate. This may be continued till the fly has required a very rapid motion. If, at this moment, a resisting body be applied to the working point, it will be acted on with very great force: for the fly has now accumulated, in its circumference, a very great momentum.

If a body were exposed immediately to the action of this circumference it would be violently struck, much more will it be so, if the body be exposed to the action of the working point, which perhaps makes one turn while the fly makes a hundred. It will exert a hundred times more force (very nearly) than at its own circumference. All the motion which has been accumulated in the fly, during the whole progress of its acceleration, is exerted in an instant at the working point, multiplied by the momentum, which depends on the proportion of the parts of the machine. It is thus that the coining press performs its office; nay, it is thus that the blacksmith forges a bar of iron. Swinging the great sledge hammer round his head, and urging it with force the whole way, this accumulated motion is at once extinguished by impact on the iron. It is thus we drive a nail; and it is thus,

thus, that by accumulating a very moderate force exerted during four or five turns of a fly, the whole of it is exerted on a punch, set on a thick plate of iron, such as is employed for the boilers of steam engines, and the plate is pierced as if it were a piece of cheese. This accumulating power of a fly has occasioned many, who think themselves engineers, to imagine, that a fly really adds power or mechanical force to an engine; and, not understanding on what its efficacy depends, they often place the fly in a situation where it only added a useless burden to the machine. If intended for a mere regulator, it should be near the first mover; if it is intended to accumulate force in the working point, it should not be far separated from it. In a certain sense, a fly may be said to add power to a machine, because by accumulating into the exertion of one moment the exertions of many, we can sometimes overcome an obstacle that we never could have balanced by the same machine unaided by the fly. See *FLY-WHEEL*.

It is this accumulation of force which gives such an appearance of power to some of our first movers. When a man is unfortunately caught by the teeth of a paltry country mill, he is crushed almost to mummy. The power of the stream is conceived to be prodigious, and yet we are

certain, upon examination, that it amounts to the pressure of no more than fifty or sixty pounds; but this force has been acting for some time, and there is a millstone of a ten weight whirling twice round in a second. This is the force that crushed the unfortunate man; and it required it all to do it, for the mill stopped. We have been informed of a mill in the neighbourhood of Elbingroda, in Hanover, where there was a contrivance which disengaged the millstone when any thing got entangled in the teeth of the wheels. On being tried with a head of cabbage, it crushed it, but not violently, and would, by no means, have broken a man's arm.

It is hardly necessary to recommend simplicity in the construction of machines. This seems now sufficiently understood. Multiplicity of motions and communications increase friction; augment the unavoidable losses by bending and yielding in every part; expose all the imperfections of workmanship; and have a great chance of being indistinctly conceived; and are therefore contractions without science. We shall consider this object as applied to large machinery under *MILL Work*.

MACHINERY for manufacturing Cotton. See *MANUFACTURE of Cotton*.
